CERMICS, France

January 25, 2015

During the night of 16 June 2013, electricity prices were negative

Outline of the talk

- In 2000, the *Optimization and Systems* team was created at École des Ponts ParisTech and, since then, we have *trained PhD students* in stochastic optimization, mostly with *Électricité de France Research and Development*
- Since 2011, we witness a growing demand from energy firms for stochastic optimization, fueled by a *deep and fast transformation of power systems*
- Renewable energies penetration, telecommunication technologies and markets remold power systems and challenge optimization
- More renewable energies → more unpredictability + more variability →
 - more storage → more dynamic optimization, optimal control
 - more stochastic optimization

hence, stochastic optimal control

- We shed light on the two main *new issues* in *stochastic control* in comparison with *deterministic* control: *risk* attitudes and online *information*
- We cast a glow on two snapshots highlighting *ongoing research* in the field of stochastic control applied to energy

Outline of the presentation

- 1 Long term industry-academy cooperation
- 2 The remolding of power systems seen from an optimizer perspective
- 3 Moving from deterministic to stochastic dynamic optimization
- 4 Two snapshots on ongoing research
- 5 A need for training and research

École des Ponts ParisTech is one of the world's oldest engineering institutes

- The **École nationale des ponts et chaussées** was founded in **1747** and is **one of the world's oldest engineering institutes**
- École des Ponts ParisTech is traditionally considered as belonging to the **5 leading engineering schools in France**
- Young graduates find positions in professional sectors like transport and urban planning, banking, finance, consulting, civil works, industry, environnement, energy. . .
- Faculty and staff
 - 217 employees (including 50 subsidiaries).
 - 165 module leaders, including 68 professors.
 - 1509 students.
- École des Ponts ParisTech is part of **University Paris-Est**

École des Ponts ParisTech hosts a substantial research activity

- Figures on research
 - Research personnel: 220
 - About 40 École des Ponts PhDs students graduate each year
- 10 research centers
 - * CEEA (atmospheric environment), joint École des Ponts-EDF R&D
 - * CEEVE (water, urban and environment studies)
 - * CERMICS (mathematics and scientific computing)
 - * CERTIS (information technologies and systems)
 - * CIIED (international environment and development)
 - * LATTS (techniques, regional planning and society)
 - * LVMT (city, mobility, transport)
 - * UR Navier (mechanics, materials and structures of civil engineering, geotechnic)
 - * Saint-Venant laboratory (fluid mechanics), joint École des Ponts-EDF R&D
 - * Paris School of Economic PSE

The CERMICS is the Centre d'enseignement et de recherche en mathématiques et calcul scientifique

- The scientific activity of CERMICS covers several domains in
 - scientific computing
 - modelling
 - optimization
- 15 senior researchers
 - 15 PhD
 - 12 habilitation à diriger des recherches
- Three missions
 - Teaching and PhD training
 - Scientific publications
 - Contracts
- 550 000 euros of contracts per year with
 - research and development centers of large industrial firms: CEA, CNES, EADS, EDF, Rio Tinto. . .
 - public research contracts

The Optimization and Systems Group comprises 3 senior researchers, as well as PhD students and external associated researchers

- Three senior researchers
 - J.-P. CHANCELIER
 - M. DE LARA
 - F. MEUNIER
- Between four and eight PhD students
- Four associated researchers
 - P. CARPENTIER (ENSTA ParisTech)
 - L. ANDRIEU (EDF R&D)
 - K. BARTY (EDF R&D)
 - A. DALLAGI (EDF R&D)

Optimization and Systems Group research specialities

• Methods

- Stochastic optimal control (discrete-time)
 - Large-scale systems
 - Discretization and numerical methods
 - Probability constraints
- Discrete mathematics; combinatorial optimization
- System control theory, viability and stochastic viability
- Numerical methods for fixed points computation
- Uncertainty and learning in economics

• Applications

- Optimized management of power systems under uncertainty (production scheduling, power grid operations, risk management)
- Transport modelling and management
- Natural resources management (fisheries, mining, epidemiology)

• Softwares

- Scicoslab, NSP
- Oadlibsim

Publications since 2000

- 24 publications in peer-reviewed international journals
- 3 publications in collective works
- 4 books
 - Modeling and Simulation in Scilab/Scicos with ScicosLab 4.4 (2e édition, Springer-Verlag)
 - Introduction à SCILAB (2e édition, Springer-Verlag)
 - Sustainable Management of Natural Resources. Mathematical Models and Methods (Springer-Verlag)
 - Control Theory for Engineers (Springer-Verlag)
- 1 book to be published by Springer-Verlag
 - *Stochastic Optimization. At the Crossroads between Stochastic Control and Stochastic Programming*

Teaching

- Masters

- *Master Parisien de Recherche Opérationnelle*
- *Optimisation & Théorie des Jeux. Modélisation en Economie*
- *Mathématiques, Informatique et Applications*
- *Économie du Développement Durable, de l'Environnement et de l'Énergie*
- *Renewable Energy Science and Technology Master ParisTech*

- École des Ponts ParisTech

- Introduction à la recherche opérationnelle (F. MEUNIER)
- Optimisation et contrôle (J.-P. CHANCELIER)
- Modéliser l'aléa (J.-P. CHANCELIER)
- Modélisation pour la gestion durable des ressources naturelles (M. DE LARA)

Industrial contracts mostly deal with energy issues, public ones touch on biodiversity management

- Industrial contracts

- Conseil français de l'énergie (CFE)
- SETEC Energy Solutions
- Électricité de France (EDF R&D)
- Thales
- Institut français de l'énergie (IFE)
- Gaz de France (GDF)
- PSA

- Public contracts

- STIC-AmSud (CNRS-INRIA-Affaires étrangères)
- Centre d'étude des tunnels
- CNRS ACI Écologie quantitative
- RTP CNRS

- 5 A need for training and research

We cooperate with industry partners, looking for longlasting research relations through training and capacity building

- As academics, we cooperate with industry partners, looking for longlasting close relations
- We are not consultants working for clients, but focus en capacity building
- Our job consists mainly in
 - training Master and PhD students, working within the company and interacting with us, on subjects designed jointly
 - developing methods, algorithms
 - contributing to computer codes developed within the company
 - training professional engineers in the company

Électricité de France R & D / Département OSIRIS

- **Électricité de France is the French electricity main producer**
 - 159 000 collaborateurs dans le monde
 - 37 millions de clients dans le monde
 - 65,2 milliards d'euros de chiffre d'affaire
 - 630,4 TWh produits dans le monde
- **Électricité de France Research & Development**
 - 486 millions d'euros de budget
 - 2 000 personnes
- **Département OSIRIS**

Optimisation, simulation, risques et statistiques pour les marchés de l'énergie
Optimization, simulation, risks and statistics for the energy markets

 - 145 salariés (dont 10 doctorants)
 - 25 millions d'euros de budget

What is “optimization”?

Optimizing is obtaining the best compromise between needs and resources

Marcel Boiteux (président d'honneur d'Électricité de France)

- **Resources:** portfolio of assets
 - production units
 - costly/not costly: thermal/hydropower
 - stock/flow, predictable/unpredictable: thermal/wind
 - tariffs options, contracts
- **Needs:** energy, safety, environment
 - energy uses
 - safety, quality, resilience (breakdowns, blackout)
 - environment protection (pollution) and alternative uses (dam water)
- **Best compromise:** minimize socio-economic costs (including externalities)

The Optimization and Systems Group has trained 10 PhD from 2004 to 2014, most of them related with EDF and energy management

- * Laetitia ANDRIEU, former PhD student at EDF, now researcher EDF
- * Kengy BARTY, former PhD student at EDF, now researcher EDF
- * Daniel CHEMLA, former PhD student
- * Anes DALLAGI, former PhD student at EDF, now researcher EDF
- * Laurent GILOTTE, former PhD student with IFE, researcher EDF
- * Pierre GIRARDEAU, former PhD student at EDF, now with ARTELYS
- * Eugénie LIORIS, former PhD student
- * Babacar SECK, former PhD student at EDF
- * Cyrille STRUGAREK, former PhD student at EDF, now with Munich-Ré
- * Jean-Christophe ALAIS, former PhD student at EDF, now with ARTELYS
- * Vincent LECLERE, former PhD student (partly at EDF), now with CERMICS

PhD subjects reflect academic issues raised by industrial problems

- *Contributions to the Discretization of Measurability Constraints for Stochastic Optimization Problems,*
- *Optimization under Probability Constraint,*
- *Uncertainty, Inertia and Optimal Decision. Optimal Control Models Applied to Greenhouse Gas Abatement Policies Selection,*
- *Variational Approaches and other Contributions in Stochastic Optimization,*
- *Particular Methods in Stochastic Optimal Control,*
- *From Risk Constraints in Stochastic Optimization Problems to Utility Functions,*
- *Resolution of Large Size Problems in Dynamic Stochastic Optimization and Synthesis of Control Laws,*
- *Evaluation and Optimization of Collective Taxis Systems,*
- *Risk and Optimization for Energies Management,*
- *Risk, Optimization, Large Systems,*

Recently, contacts have expanded with small companies

- **ARTELYS** is a company specializing in **optimization, decision-making and modeling**. Relying on their high level of **expertise in quantitative methods**, the consultants deliver efficient solutions to complex business problems. They provide services to diversified industries: **Energy & Environment**, Logistics & Transportation, Telecommunications, Finance and Defense.
- Créée en 2011, **SETEC Energy Solutions** est la filiale du groupe SETEC spécialisée dans les domaines de la **production** et de la **maîtrise de l'énergie** en France et à l'étranger. SETEC Energy Solutions apporte à ses clients la maîtrise des principaux process énergétiques pour la mise en œuvre de solutions innovantes depuis les phases initiales de définition d'un projet jusqu'à son exploitation.
- **SUN'R Smart Energy** is a Paris based company with a focus on building smarter solutions for **distributed energy resources** in the context of emerging deregulated energy markets and a solid political will towards the development of both renewables and energy storage. The company is part of a larger group founded in 2007 and is a growing, well-funded early stage business.

French Energy Council, member of the World Energy Council, contracted the Optimization and Systems group to report on Optimization methods for smart grids

- Formed in 1923, the **World Energy Council** (WEC) is the UN-accredited global energy body, representing the entire energy spectrum, with more than 3000 member organisations located in over 90 countries and drawn from governments, private and state corporations, academia, NGOs and energy-related stakeholders
- WEC informs global, regional and national energy strategies by hosting high-level events, publishing authoritative studies, and working through its extensive member network to facilitate the world's energy policy dialogue
- In 2012, the **French Energy Council** contracted the Optimization and Systems group to produce a report on **Optimization methods for smart grids**

Summary

The following slides on the remolding of power systems express a viewpoint

- from an optimizer perspective
- working in an optimization research group
- in an applied mathematics research center
- in a French engineering institute
- having contributed to train students now working in energy
- having contacts and contracts with energy/environment firms

Three key drivers are remolding power systems

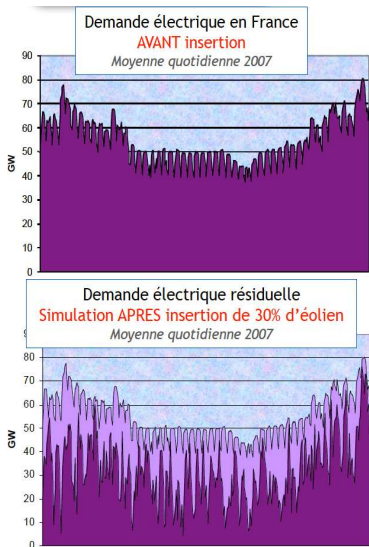

- Environment
- Markets
- Technology

● Multiple levels of integration – interoperability
● Distributed Generation ● Renewable Generation ● Storage ● Demand Response

Key driver: environmental concern

The European Union climate and energy package materializes an environmental concern with three 20-20-20 objectives for 2020

- a 20% improvement in the EU's energy efficiency
- a 20% reduction in EU greenhouse gas emissions from 1990 levels
- raising the share of EU energy consumption produced from renewable resources to 20%

Successfully integrating renewable energy sources has become critical, and made especially difficult because they are unpredictable and highly variable, hence triggering the use of local storage

Key driver: economic deregulation

- A **power system** (generation/transmission/distribution)
 - **less and less vertical** (deregulation of energy markets)
 - hence with **many players with their own goals**
- with some **new players**
 - industry (electric vehicle)
 - regional public authorities (autonomy, efficiency)
- with a **network in horizontal expansion**
(the Pan European electricity transmission system counts 10,000 buses, 15,000 power lines, 2,500 transformers, 3,000 generators, 5,000 loads)
- with more and more exchanges (trade of commodities)

A **change of paradigm for management**
from **centralized to more and more decentralized**

Key driver: telecommunication technology

Linky

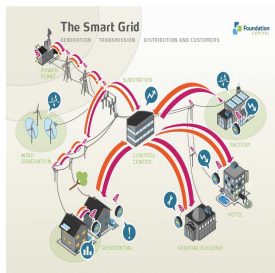

A power system with **more and more technology** due to evolutions in the fields of metering, computing and telecoms

- smart meters
- sensors
- controllers
- grid communication devices. . .

A **huge amount of data** which, one day, will be a new **potential for optimized management**

The “smart grid”? An infrastructure project with promises to be fulfilled by a “smart power system”

- **Hardware** / infrastructures / smart technologies
 - Renewable energies technologies
 - Smart metering
 - Storage
- **Promises**
 - Quality, tariffs
 - More safety
 - More renewables (environmentally friendly)
- **Software** / smart management
(energy supply being less flexible, make the demand more flexible)

smart management, smart operation, smart meter management, smart distributed generation, load management, advanced distribution management systems, active demand management, diffuse effacement, distribution management systems, storage management, smart home, demand side management. . .

We witnessed a call from EDF to optimizers

- Every three years, **Électricité de France (EDF)** organizes an **international Conference on Optimization and Practices in Industry (COPI)**
- At COPI'11, Jean-François Faugeras from EDF R&D opened the conference with a **plenary talk** entitled **“Smart grids: a wind of change in power systems and new opportunities for optimization”**
- He claimed that **“power system players are facing high level problems to solve requiring new optimization methods and tools”**, with **“not only a 'smart(er)' grid but a 'smart(er)' power system”** and called on the optimizers to develop new methods
- In 2012, **EDF R&D** has sponsored a **new program** *Gaspard Monge pour l'Optimisation et la recherche opérationnelle* (PGMO) to **support academic research in the field of optimization**

What is “optimization”?

Optimizing is obtaining the best compromise between needs and resources

Marcel Boiteux (président d'honneur d'Électricité de France)

- **Resources:** portfolio of assets
 - production units
 - costly/not costly: thermal/hydropower
 - stock/flow, predictable/unpredictable: thermal/wind
 - tariffs options, contracts
- **Needs:** energy, safety, environment
 - energy uses
 - safety, quality, resilience (breakdowns, blackout)
 - environment protection (pollution) and alternative uses (dam water)
- **Best compromise:** minimize socio-economic costs (including externalities)

Electrical engineers metiers and skills are evolving

- **Unit commitment**, optimal **dispatch** of generating units:
finding the least-cost dispatch of available generation resources to meet the electrical load
 - which unit? 0/1 variables
 - which power level? continuous variables

subject to more unpredictable energy flows (solar, wind)
and demand (electrical devices, cars)
- **Markets: day-ahead, intra-day** (balancing market):
dispatcher takes bids from the generators, demand forecasts from the distribution companies and clears the market
subject to more unpredictability, more players
- **Long term planning**
subject to more unpredictability (technologies, climate), more players
- ... Without even speaking of voltage, frequency and phase control

Let us have a look at economic dispatch (static) as a cost-minimization problem under supply-demand balance

Consider energy production units $i = 1, \dots, N$, like coal, gas, nuclear...

$$\underbrace{\min_{(u_1, \dots, u_N)} \sum_{i=1}^N J_i(u_i)}_{\text{costs minimization}} \quad \text{under} \quad \underbrace{\sum_{i=1}^N \Theta_i(u_i) = D}_{\text{supply = demand}}$$

where

- u_i is the **decision** (production level) made for each unit i
- $J_i(u_i)$ is the **cost** of making decision u_i for unit i
- $\Theta_i(u_i)$ is the **production** induced by making decision u_i for unit i
- D is the demand

Inviting in uncertainty gives economic dispatch new suits of clothes

$$\underbrace{\min_{(u_1, \dots, u_N)} \mathbb{E} \left[\sum_{i=1}^N J_i(u_i, \overbrace{p_i}^{\text{price}}) \right]}_{\text{expected costs minimization}} \quad \text{under} \quad \underbrace{\sum_{i=1}^N \Theta_i(u_i, \overbrace{w_i}^{\text{weather}}) = \overbrace{D}^{\text{demand}}}_{\text{almost-surely supply = demand}}$$

- Mathematical description of sources of uncertainties (prices p_i , weather w_i , demand D , failures...): statistics? bounds?
- Mathematical formulation of the criterion under uncertainty: in expectation (\mathbb{E})? worst case (max)?
- Mathematical formulation of the constraints under uncertainty: in expectation? in probability? almost surely? robust? by penalization?

With uncertainty come stages, hence a dynamics

- In electricity, the *supply matches demand* equation “is like gravity, you cannot negotiate” (who claimed that?)
- One way or another, we are driven to add a new instantaneous source u_{N+1}

$$\sum_{i=1}^N \Theta_i(u_i, \underbrace{w_i}_{\text{weather}}) + \underbrace{u_{N+1}}_{\text{new source}} = \underbrace{D}_{\text{demand}}$$

- The control $u_{N+1} = D - \sum_{i=1}^N \Theta_i(u_i, w_i)$ depends on the uncertain variables D and w_1, \dots, w_N
- Whereas u_1, \dots, u_N are decisions made **before** knowing their realizations
- To cut to the point, we now have **two stages**

Piecing things together, we started from static economic dispatch and, on the path of making allowance for uncertainty, we have been quite naturally led to **dynamic** economic dispatch under **risk**

Optimization skills will follow the power system evolution

We focus on generation and trading, not on transmission and distribution

- Less base production and **more wind and photovoltaic fatal generation** makes supply more unpredictable
→ **stochastic** optimization
- Hence more **storage** (batteries, pumping stations)
→ **dynamical** optimization, reserves **dimensioning**
- The **shape of the load is changing** due to electric vehicle penetration
→ **demand-side management**, “peak shaving”, **adaptive tariffs**
- **New subsystems emerge** with local information and means of action: smart meters, new producers, **micro-grid**, **virtual power plant**
→ **agregation**, **coordination**, **decentralized** optimization
- **Markets** (day-ahead, intra-day)
→ optimization under uncertainty
- **Environmental constraints** on production (CO₂) and resources usages (water)
→ **risk constraints**

Summary

- Three major key factors — **environmental** concern, **deregulation**, telecommunication, metering and computing **technology** — drive the **power systems remolding**
- This remolding induces a **change of paradigm for management**: from vertical centralized predictable “stock” energies to more horizontal decentralized unpredictable variable “flow” energies
- **Specific optimization skills** will be required, because a deterministic optimal solution is *balancing on a knife edge*, hence might perform poorly under off-nominal conditions, like a *too much adjusted suit cracking at the first move*

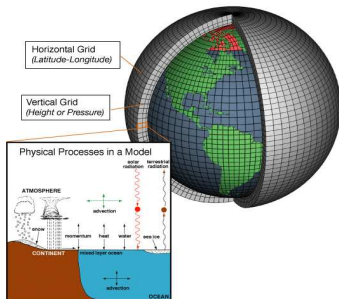

Roger Wets' illuminating example: deterministic vs. robust

of a furniture manufacturer deciding how many dressers of each of 4 types to produce, with carpentry and finishing man-hours as constraints; when the ten parameters become random, the stochastic optimal solution considers all $\approx 10^6$ possibilities and provides a robust solution (257 ; 0 ; 665 ; 34), whereas the deterministic solution (1,333 ; 0 ; 0 ; 67) does not point in the right direction

Outline of the presentation

- 1 Long term industry-academy cooperation
- 2 The remolding of power systems seen from an optimizer perspective
- 3 Moving from deterministic to stochastic dynamic optimization**
- 4 Two snapshots on ongoing research
- 5 A need for training and research

We distinguish two polar classes of models: knowledge models *versus* decision models

Knowledge models:

1/1 000 000 → 1/1 000 → 1/1 maps

Office of Oceanic and Atmospheric
Research (OAR) climate model

Let us work out a toy example of economic dispatch as a cost-minimization problem under supply-demand balance

- **Production:** consider two energy production units
 - a “cheap” limited one with which we can produce quantity q_0 , with $0 \leq q_0 \leq q_0^\#$, at cost $c_0 q_0$
 - an “expensive” unlimited one with which we can produce quantity q_1 , with $0 \leq q_1$, at cost $c_1 q_1$, with $c_1 > c_0$
- **Consumption:** the demand is $D \geq 0$
- **Balance:** ensuring at least the demand

$$D \leq q_0 + q_1$$

- **Optimization:** total costs minimization

$$\min_{q_0, q_1} \underbrace{c_0 q_0 + c_1 q_1}_{\text{total costs}}$$

When the demand D is deterministic, the optimization problem is well posed

- The deterministic demand D is a single number, and we consider

$$\min_{q_0, q_1} c_0 q_0 + c_1 q_1$$

under the constraints

$$\begin{aligned} 0 &\leq q_0 \leq q_0^\sharp \\ 0 &\leq q_1 \\ D &\leq q_0 + q_1 \end{aligned}$$

- The solution is $q_0^* = \min\{q_0^\sharp, D\}$, $q_1^* = [D - q_0^\sharp]_+$, that is,
 - if the demand D is below the capacity q_0^\sharp of the “cheap” energy source

$$D \leq q_0^\sharp \Rightarrow q_0^* = D, \quad q_1^* = 0$$

- if the demand D is above the capacity q_0^\sharp of the “cheap” energy source,

$$D > q_0^\sharp \Rightarrow q_0^* = q_0^\sharp, \quad q_1^* = D - q_0^\sharp$$

- Now, what happens when the demand D is no longer deterministic?

If we know the demand beforehand, the optimization problem is deterministic

- We suppose that the demand is a random variable $D : \Omega \rightarrow \mathbb{R}_+$
- If we solve the problem for each possible value $D(\omega)$ of the random variable D , when $\omega \in \Omega$, we obtain

$$q_0(\omega) = \min\{q_0^\#, D(\omega)\}, \quad q_1(\omega) = [D(\omega) - q_0^\#]_+$$

and we face an **informational issue**

- Indeed, we treat the demand D as if it were **observed before making the decisions** q_0 and q_1
- When the demand D is not observed, how can we do?

What happens if we replace the uncertain value D of the demand by its mean \bar{D} in the deterministic solution?

- If we suppose that the demand D is a random variable $D : \Omega \rightarrow \mathbb{R}_+$, with mathematical expectation $\mathbb{E}(D) = \bar{D}$
- and that we propose the “deterministic solution”

$$q_0^{(\bar{D})} = \min\{q_0^\#, \bar{D}\}, \quad q_1^{(\bar{D})} = [\bar{D} - q_0^\#]_+$$

- we cannot assure the inequality

$$\underbrace{D(\omega)}_{\text{uncertain}} \leq \underbrace{q_0 + q_1}_{\text{deterministic}}, \quad \forall \omega \in \Omega$$

because $\sup_{\omega \in \Omega} D(\omega) > \bar{D} = q_0^{(\bar{D})} + q_1^{(\bar{D})}$

- Are there better solutions among the deterministic ones?

When the demand D is bounded above, the robust optimization problem has a solution

- In the robust optimization problem, we minimize

$$\min_{q_0, q_1} c_0 q_0 + c_1 q_1$$

under the constraints

$$\begin{aligned} 0 &\leq q_0 \leq q_0^\# \\ 0 &\leq q_1 \\ D(\omega) &\leq q_0 + q_1, \quad \forall \omega \in \Omega \end{aligned}$$

- When $D^\# = \sup_{\omega \in \Omega} D(\omega) < +\infty$, the solution is $q_0^* = \min\{q_0^\#, D^\#\}$, $q_1^* = [D^\# - q_0^\#]_+$
- Now, the total cost $c_0 q_0^* + c_1 q_1^*$ is an increasing function of the upper bound $D^\#$ of the demand
- Is it not too costly to optimize under the worst-case situation?

Where do we stand?

- When the demand D is deterministic, the optimization problem is well posed
- If we know the demand beforehand, the optimization problem is deterministic
- If we replace the uncertain value D of the demand by its mean \bar{D} in the deterministic solution, we remain with a **feasibility issue**
- When the demand D is bounded above, the **robust** optimization problem has a solution, but it is **costly**

Where do we stand?

- When the demand D is deterministic, the optimization problem is well posed
- If we know the demand beforehand, the optimization problem is deterministic
- If we replace the uncertain value D of the demand by its mean \bar{D} in the deterministic solution, we remain with a **feasibility issue**
- When the demand D is bounded above, the **robust** optimization problem has a solution, but it is **costly**

To overcome the above difficulties, we propose to introduce **stages**

$$\underbrace{D(\omega)}_{\text{uncertain}} \leq \underbrace{q_0}_{\text{deterministic}} + \underbrace{q_1(\omega)}_{\text{uncertain}}, \quad \forall \omega \in \Omega$$

- the decision q_0 is made **before observing** the demand $D(\omega)$
- the decision $q_1(\omega)$ is made **after observing** the demand $D(\omega)$

To overcome the above difficulties, we turn to stochastic optimization

- We suppose that the demand D is a random variable, and minimize

$$\min_{q_0, q_1} \mathbb{E}[c_0 q_0 + c_1 q_1]$$

under the constraints

$$\begin{aligned} 0 &\leq q_0 \leq q_0^\# \\ 0 &\leq q_1 \\ D &\leq q_0 + q_1 \\ q_1 &\text{ depends upon } D \end{aligned}$$

and we emphasize two issues, new with respect to the deterministic case

- expliciting online information issue:**
the decision q_1 depends upon the random variable D
- expliciting risk attitudes:**
we aggregate the total costs with respect to all possible values
by taking the expectation $\mathbb{E}[c_0 q_0 + c_1 q_1]$

Turning to stochastic optimization forces one to specify online information

- We suppose that the demand D is a random variable, and minimize

$$\min_{q_0, q_1} \mathbb{E}[c_0 q_0 + c_1 q_1]$$

under the constraints

$$0 \leq q_0 \leq q_0^\#$$

$$0 \leq q_1$$

$$D \leq q_0 + q_1$$

q_1 depends upon D

- specifying that the decision q_1 depends upon the random variable D , whereas q_0 does not, forces to consider **two stages** and a so-called **non-anticipativity constraint** (more on that later)
 - first stage: q_0 does not depend upon the random variable D
 - second stage: q_1 depends upon the random variable D

Turning to stochastic optimization forces one to specify risk attitudes

- We suppose that the demand D is a random variable, and minimize

$$\min_{q_0, q_1} \mathbb{E}[c_0 q_0 + c_1 q_1]$$

under the constraints

$$\begin{aligned} 0 &\leq q_0 \leq q_0^\# \\ 0 &\leq q_1 \\ D &\leq q_0 + q_1 \\ q_1 &\text{ depends upon } D \end{aligned}$$

- Now that q_1 depends upon the random variable D , it is also a random variable, and so is the total cost $c_0 q_0 + c_1 q_1$; therefore, we have to **aggregate the total costs** with respect to all possible values, and we chose to do it by taking the expectation $\mathbb{E}[c_0 q_0 + c_1 q_1]$

In the uncertain framework,
two additional questions must be answered
with respect to the deterministic case

Question (expliciting risk attitudes)

How are the uncertainties taken into account
in the payoff criterion and in the constraints?

Question (expliciting available online information)

Upon which online information are decisions made?

The output of a stochastic optimization problem is a random variable. How can we rank random variables?

How are the uncertainties taken into account in the payoff criterion and in the constraints?

In a **probabilistic setting**, where uncertainties are random variables, a classical answer is

- to take the **mathematical expectation** of the payoff (risk-neutral approach)

$$\mathbb{E}(\text{payoff})$$

- and to satisfy all (physical) constraints **almost surely** that is, practically, for all possible issues of the uncertainties (**robust approach**)

$$\mathbb{P}(\text{constraints}) = 1$$

But there are many other ways to handle risk: robust, worst case, risk measures, in probability, almost surely, by penalization, etc.

A policy and a criterion yield a real-valued payoff

Given an admissible policy $\text{Pol} \in \mathcal{U}^{ad}$ and a scenario $w(\cdot) \in \Omega$, we obtain a payoff

$$\text{Payoff}(\text{Pol}, w(\cdot))$$

Policies/Scenarios	$w^A(\cdot) \in \Omega$	$w^B(\cdot) \in \Omega$...
$\text{Pol}_1 \in \mathcal{U}^{ad}$	$\text{Payoff}(\text{Pol}_1, w^A(\cdot))$	$\text{Payoff}(\text{Pol}_1, w^B(\cdot))$...
$\text{Pol}_2 \in \mathcal{U}^{ad}$	$\text{Payoff}(\text{Pol}_2, w^A(\cdot))$	$\text{Payoff}(\text{Pol}_2, w^B(\cdot))$...
...

In the robust or pessimistic approach,
Nature is supposed to be malevolent,
and the DM aims at protection against all odds

In the robust or pessimistic approach, Nature is supposed to be malevolent

- In the robust approach, the DM considers the **worst payoff**

$$\underbrace{\min_{w(\cdot) \in \Omega} \text{Payoff}(\text{Pol}, w(\cdot))}_{\text{worst payoff}}$$

- Nature is supposed to be malevolent,
and specifically selects the worst scenario:
the DM plays after Nature has played, and maximizes the worst payoff

$$\max_{\text{Pol} \in \mathcal{U}^{ad}} \min_{w(\cdot) \in \Omega} \text{Payoff}(\text{Pol}, w(\cdot))$$

- Robust, pessimistic, worst-case, maximin, minimax (for costs)

Guaranteed energy production

In a dam, the minimal energy production in a given period, corresponding to the worst water inflow scenario

The robust approach can be softened with plausibility weighting

- Let $\Theta : \Omega \rightarrow \mathbb{R} \cup \{-\infty\}$ be a **plausibility function**.
- The higher, the more plausible:
totally **implausible scenarios** are those for which $\Theta(w(\cdot)) = -\infty$
- Nature is malevolent, and specifically selects the worst scenario, but weighs it according to the plausibility function Θ
- The DM plays after Nature has played, and solves

$$\max_{\text{Pol} \in \mathcal{U}^{ad}} \left[\min_{w(\cdot) \in \Omega} \left(\text{Payoff}(\text{Pol}, w(\cdot)) - \underbrace{\Theta(w(\cdot))}_{\text{plausibility}} \right) \right]$$

In the optimistic approach, Nature is supposed to be benevolent

*Future. That period of time in which our affairs prosper,
our friends are true and our happiness is assured.*

Ambrose Bierce

- Instead of maximizing the worst payoff as in a robust approach, the optimistic focuses on the **most favorable payoff**

$$\underbrace{\max_{w(\cdot) \in \Omega} \text{Payoff}(\text{Po1}, w(\cdot))}_{\text{best payoff}}$$

- **Nature is supposed to be benevolent**, and specifically selects the best scenario: the DM plays after Nature has played, and solves

$$\max_{\text{Po1} \in \mathcal{U}^{ad}} \max_{w(\cdot) \in \Omega} \text{Payoff}(\text{Po1}, w(\cdot))$$

The Hurwicz criterion reflects an intermediate attitude between optimistic and pessimistic approaches

A proportion $\alpha \in [0, 1]$ graduates the level of prudence

$$\max_{\text{Pol} \in \mathcal{U}^{ad}} \left\{ \alpha \overbrace{\min_{w(\cdot) \in \Omega} \text{Payoff}(\text{Pol}, w(\cdot))}^{\text{pessimistic}} + (1 - \alpha) \underbrace{\max_{w(\cdot) \in \Omega} \text{Payoff}(\text{Pol}, w(\cdot))}_{\text{optimistic}} \right\}$$

In the stochastic or expected approach,
Nature is supposed to play stochastically

In the stochastic or expected approach, Nature is supposed to play stochastically

- The **expected payoff** is

$$\overbrace{\mathbb{E} \left[\text{Payoff}(\text{Pol}, w(\cdot)) \right]}^{\text{mean payoff}} = \sum_{w(\cdot) \in \Omega} \mathbb{P}\{w(\cdot)\} \text{Payoff}(\text{Pol}, w(\cdot))$$

- Nature is supposed to play stochastically, according to distribution \mathbb{P} : the DM plays after Nature has played, and solves

$$\max_{\text{Pol} \in \mathcal{U}^{ad}} \mathbb{E} \left[\text{Payoff}(\text{Pol}, w(\cdot)) \right]$$

- The **discounted expected utility** is the special case

$$\mathbb{E} \left[\sum_{t=t_0}^{+\infty} \delta^{t-t_0} L(x(t), u(t), w(t)) \right]$$

The expected utility approach distorts payoffs before taking the expectation

- We consider a **utility function** L to assess the utility of the payoffs (for instance a CARA exponential utility function)
- The **expected utility** is

$$\underbrace{\mathbb{E} \left[L \left(\text{Payoff}(\text{Pol}, w(\cdot)) \right) \right]}_{\text{expected utility}} = \sum_{w(\cdot) \in \Omega} \mathbb{P}\{w(\cdot)\} L \left(\text{Payoff}(\text{Pol}, w(\cdot)) \right)$$

- The **expected utility maximizer** solves

$$\max_{\text{Pol} \in \mathcal{U}^{ad}} \mathbb{E} \left[L \left(\text{Payoff}(\text{Pol}, w(\cdot)) \right) \right]$$

The ambiguity or multi-prior approach combines robust and expected criterion

- Different probabilities \mathbb{P} , termed as beliefs or priors and belonging to a set \mathcal{P} of admissible probabilities on Ω
- The multi-prior approach combines robust and expected criterion by taking the worst beliefs in terms of expected payoff

$$\max_{\text{Pol} \in \mathcal{U}^{ad}} \min_{\mathbb{P} \in \mathcal{P}} \overbrace{\mathbb{E}^{\mathbb{P}} \left[\text{Payoff}(\text{Pol}, w(\cdot)) \right]}^{\text{mean payoff}}$$

pessimistic over probabilities

Convex risk measures cover a wide range of risk criteria

- Different probabilities \mathbb{P} , termed as beliefs or priors and belonging to a set \mathcal{P} of admissible probabilities on Ω
- To each probability \mathbb{P} is attached a plausibility $\Theta(\mathbb{P})$

$$\max_{\text{Pol} \in \mathcal{U}^{ad}} \underbrace{\min_{\mathbb{P} \in \mathcal{P}} \mathbb{E}^{\mathbb{P}} \left[\text{Payoff}(\text{Pol}, w(\cdot)) \right]}_{\text{pessimistic over probabilities}} - \underbrace{\Theta(\mathbb{P})}_{\text{plausibility}}$$

Non convex risk measures can lead to non diversification

How to gamble if you must,
L.E. Dubbins and L.J. Savage,
1965

Imagine yourself at a casino with \$1,000. For some reason, you desperately need \$10,000 by morning; anything less is worth nothing for your purpose.

The only thing possible is to gamble away your last cent, if need be, in an attempt to reach the target sum of \$10,000.

- The question is how to play, not whether. What ought you do? How should you play?
 - Diversify, by playing 1 \$ at a time?
 - Play boldly and concentrate, by playing 10,000 \$ only one time?
- What is your decision criterion?

Savage's minimal regret criterion... "Had I known"

$$\min_{\text{Pol} \in \mathcal{U}^{ad}} \left\{ \max_{w(\cdot) \in \Omega} \left[\max_{\text{anticipative policies } \overline{\text{Pol}}} \text{Payoff}(\overline{\text{Pol}}, w(\cdot)) - \text{Payoff}(\text{Pol}, w(\cdot)) \right] \right\}$$

worst regret

regret

- If the DM knows the future in advance, she solves $\max_{\text{anticipative policies } \overline{\text{Pol}}} \text{Payoff}(\overline{\text{Pol}}, w(\cdot))$, for each scenario $w(\cdot) \in \Omega$
- The regret attached to a non-anticipative policy $\text{Pol} \in \mathcal{U}^{ad}$ is the loss due to not being visionary
- The best a non-visionary DM can do with respect to regret is minimizing it

Outline of the presentation

- 1 Long term industry-academy cooperation
 - Ecole des Ponts ParisTech–Cermics–Optimization and Systems
 - Industry partners of the Optimization and Systems Group
- 2 The remolding of power systems seen from an optimizer perspective
 - The remolding of power systems
 - Optimization is challenged
- 3 Moving from deterministic to stochastic dynamic optimization
 - Working out a toy example
 - Expliciting risk attitudes
 - **Handling online information**
 - Discussing framing and resolution methods
- 4 Two snapshots on ongoing research
 - Decomposition-coordination optimization methods under uncertainty
 - Risk constraints in optimization
- 5 A need for training and research

Upon which online information are decisions made?

We navigate between two stumbling blocks: rigidity and wizardry

- On the one hand, it is **suboptimal** to restrict oneself, as in the deterministic case, to **open-loop controls** depending only upon time, thereby **ignoring the available information at the moment of making a decision**
- On the other hand, it is impossible to suppose that we know in advance what will happen for all times: **clairvoyance is impossible** as well as look-ahead solutions

The in-between is **non-anticipativity constraint**

There are two ways to express the non-anticipativity constraint

Denote the **uncertainties** at time t by $w(t)$, and the **control** by $u(t)$

- **Functional approach**

The control $u(t)$ may be looked after under the form

$$u(t) = \phi_t \left(\underbrace{w(t_0), \dots, w(t-1)}_{\text{past}} \right)$$

where ϕ_t is a function, called **policy**, **strategy** or **decision rule**

- **Algebraic approach**

When uncertainties are considered as **random variables** (measurable mappings), the above formula for $u(t)$ expresses the **measurability** of the control variable $u(t)$ with respect to the past uncertainties, also written as

$$\underbrace{\sigma(u(t))}_{\sigma\text{-algebra}} \subset \underbrace{\sigma(w(t_0), \dots, w(t-1))}_{\text{past}}$$

What is a solution at time t ?

- In deterministic control, the solution $u(t)$ at time t is a single vector
- In stochastic control, the solution $u(t)$ at time t is a **random variable** expressed

- either as $u(t) = \phi_t(w(t_0), \dots, w(t-1))$, where $\phi_t : \mathbb{W}^{t-t_0} \rightarrow \mathbb{R}$

- or as $u(t) : \Omega \rightarrow \mathbb{R}$ with measurability constraint

$\sigma(u(t)) \subset \sigma(w(t_0), \dots, w(t-1))$ or

$$u(t) = \mathbb{E} \left(u(t) \mid w(t_0), \dots, w(t-1) \right)$$

- Now, **as time t goes on**, the domain of the function ϕ_t **expands**, and so do the conditions $\sigma(u(t)) \subset \sigma(w(t_0), \dots, w(t-1))$
- Therefore, for numerical reasons, **the information $(w(t_0), \dots, w(t-1))$ has to be compressed or approximated**

Scenarios can be organized like a comb or like a tree

There are two classical ways to compress information

- **State-based functional approach**

In the special case of the **Markovian** framework with $(w(t_0), \dots, w(T))$ **white noise**, there is **no loss of optimality** to look for solutions as

$$u(t) = \psi_t \underbrace{(x(t))}_{\text{state}} \quad \text{where} \quad \underbrace{x(t) \in \mathbb{X}}_{\text{fixed space}}, \quad \underbrace{x(t+1) = F_t(x(t), u(t), w(t))}_{\text{dynamical equation}}$$

- **Scenario-based measurability approach**

Scenarios are approximated by a finite family $(w^s(t_0), \dots, w^s(T))$, $s \in S$

- Either **solutions** $u^s(t)$ are indexed by $s \in S$ with the constraint that

$$(w^s(t_0), \dots, w^{s'}(t-1)) = (w^{s'}(t_0), \dots, w^{s'}(t-1)) \Rightarrow u^s(t) = u^{s'}(t)$$

- Or — in the case of the **scenario tree approach**, where the scenarios $(w^s(t_0), \dots, w^s(T))$, $s \in S$, are organized in a tree — **solutions** $u^n(t)$ are **indexed by nodes** n on the tree

More on what is a solution at time t

State-based approach $u(t) = \psi_t(x(t))$

- The mapping ψ_t can be computed in advance (that is, at initial time t_0) and evaluated at time t on the available online information at that time t
 - either exactly (for example, by dynamic programming)
 - or approximately (for example, among linear decision rules) because the computational burden of finding *any* function is heavy
- The value $u(t) = \psi_t(x(t))$ can be computed at time t
 - either exactly by solving a proper optimization problem, which raises issues of dynamic consistency
 - or approximately (for example, by assuming that controls from time t on are open-loop)

More on what is a solution at time t

Scenario-based approach

- An optimal “solution” can be computed scenario by scenario, with the problem that we obtain solutions such that

$$(w^s(t_0), \dots, w^s(t-1)) = (w^{s'}(t_0), \dots, w^{s'}(t-1)) \text{ and } u^s(t) \neq u^{s'}(t)$$

- Optimal solutions can be **computed scenario by scenario** and then **merged** (for example, by Progressive Hedging) to be **forced** to satisfy

$$(w^s(t_0), \dots, w^s(t-1)) = (w^{s'}(t_0), \dots, w^{s'}(t-1)) \Rightarrow u^s(t) = u^{s'}(t)$$

- The value $u(t)$ can be computed at time t depending on $(w^s(t_0), \dots, w^s(t-1))$
 - either exactly by solving a proper optimization problem, which raises issues of dynamic consistency
 - or approximately (for example, by a sequence of two-stages problems)

Outline of the presentation

- 1 Long term industry-academy cooperation
 - Ecole des Ponts ParisTech–Cermics–Optimization and Systems
 - Industry partners of the Optimization and Systems Group
- 2 The remolding of power systems seen from an optimizer perspective
 - The remolding of power systems
 - Optimization is challenged
- 3 Moving from deterministic to stochastic dynamic optimization
 - Working out a toy example
 - Expliciting risk attitudes
 - Handling online information
 - Discussing framing and resolution methods
- 4 Two snapshots on ongoing research
 - Decomposition-coordination optimization methods under uncertainty
 - Risk constraints in optimization
- 5 A need for training and research

Where do we stand?

- How one frames the non-anticipativity constraint impacts numerical resolution methods
- On a finite scenario space, one obtains large (deterministic) optimization problems either on a tree or on a comb
- Else, one resorts to state-based formulations, with solutions as policies (dynamic programming)

Optimization approaches to attack complexity

Linear programming

- linear equations and inequalities
- no curse of dimension

Stochastic programming

- no special treatment of time and uncertainties
- no independence assumption
- decisions are indexed by a scenario tree
- what if information is not a node in the tree?

State-based dynamic optimization

- nonlinear equations and inequalities
- curse of dimensionality
- independence assumption on uncertainties
- special treatment of time (dynamic programming equation)
- decisions are indexed by an information state (feedback synthesis)
- an information state summarizes past controls and uncertainties
- decomposition-coordination methods to overcome the curse of dimensionality?

Summary

- *Stochastic* optimization highlights **risk attitudes** tackling
- Stochastic *dynamic* optimization emphasizes the handling of **online information**
- Many issues are raised, because
 - many ways to represent risk (criterion, constraints)
 - many information structures
 - tremendous numerical obstacles to overcome
- Each method has its **numerical wall**
 - in dynamic programming, the bottleneck is the dimension of the state (no more than 3)
 - in stochastic programming, the bottleneck is the number of stages (no more than 2)

Decomposition-coordination: divide and conquer

- **Spatial** decomposition
 - Multiple players with their local information
 - Scales: local / regional / national /supranational
- **Temporal** decomposition
 - A **state** is an **information summary**
 - Time coordination realized through **Dynamic Programming**, by value functions
 - Hard nonanticipativity constraints
- **Scenario** decomposition
 - Along each scenario, **sub-problems** are **deterministic** (powerful algorithms)
 - Scenario coordination realized through **Progressive Hedging**, by updating nonanticipativity multipliers
 - Soft nonanticipativity constraints

Coupling constraints: an overview

$$\min_{\mathbf{x}, \mathbf{u}} \sum_{s=1}^S \sum_{i=1}^N \sum_{t=0}^T \pi_s L_{i,t}(\mathbf{x}_{i,t}, \mathbf{u}_{i,t}, \mathbf{w}_t)$$

Coupling constraints: time coupling

$$\min_{\mathbf{x}, \mathbf{u}} \sum_{s=1}^S \sum_{i=1}^N \sum_{t=0}^T L_{i,t}(\mathbf{x}_{i,t}, \mathbf{u}_{i,t}, \mathbf{w}_t)$$

$$\text{s.t. } \mathbf{x}_{i,t+1} = f_{i,t}(\mathbf{x}_{i,t}, \mathbf{u}_{i,t}, \mathbf{w}_t)$$

Coupling constraints: scenario coupling

$$\min_{\mathbf{x}, \mathbf{u}} \sum_{s=1}^S \sum_{i=1}^N \sum_{t=0}^T L_{i,t}(\mathbf{x}_{i,t}, \mathbf{u}_{i,t}, \mathbf{w}_t)$$

$$\text{s.t. } \mathbf{x}_{i,t+1} = f_{i,t}(\mathbf{x}_{i,t}, \mathbf{u}_{i,t}, \mathbf{w}_t)$$

$$\sigma(\mathbf{u}_{i,t}) \subset \sigma(\mathbf{w}_0, \dots, \mathbf{w}_t)$$

Coupling constraints: space coupling

$$\min_{\mathbf{x}, \mathbf{u}} \sum_{s=1}^S \sum_{i=1}^N \sum_{t=0}^T L_{i,t}(\mathbf{x}_{i,t}, \mathbf{u}_{i,t}, \mathbf{w}_t)$$

$$\text{s.t. } \mathbf{x}_{i,t+1} = f_{i,t}(\mathbf{x}_{i,t}, \mathbf{u}_{i,t}, \mathbf{w}_t)$$

$$\sigma(\mathbf{u}_{i,t}) \subset \sigma(\mathbf{w}_0, \dots, \mathbf{w}_t)$$

$$\sum_{i=1}^N \theta_{i,t}(\mathbf{x}_{i,t}, \mathbf{u}_{i,t}, \mathbf{w}_t) = 0$$

Decomposition/coordination methods: an overview

Main idea

- 1 **decompose** a large scale problem into smaller subproblems we are able to solve by efficient algorithms
- 2 **coordinate** the subproblems for the concatenation of their solutions to form the initial problem solution

How to decompose the problem by duality?

- 1 **identify** the coupling dimensions of the problem:
time, uncertainty, space
- 2 **dualize** the coupling constraints by introducing **multipliers**
- 3 **split** the problem into the resulting subproblems and **coordinate** them by means of the multiplier

In the case of **time decomposition**, we can use the time arrow to **chain** static subproblems by the dynamics equation (without dualizing)

Decomposition/coordination methods: an overview

$$\min_{\mathbf{x}, \mathbf{u}} \mathbb{E} \left(\sum_{i=1}^N \sum_{t=0}^T L_{i,t}(\mathbf{x}_{i,t}, \mathbf{u}_{i,t}, \mathbf{w}_t) \right)$$

$$\text{s.t. } \mathbf{x}_{i,t+1} = f_{i,t}(\mathbf{x}_{i,t}, \mathbf{u}_{i,t}, \mathbf{w}_t)$$

$$\mathbf{u}_{i,t} = \mathbb{E}(\mathbf{u}_{i,t} \mid \mathbf{w}_0, \dots, \mathbf{w}_t)$$

$$\sum_{i=1}^N \theta_{i,t}(\mathbf{x}_{i,t}, \mathbf{u}_{i,t}, \mathbf{w}_t) = 0$$

Decomposition/coordination methods: time coupling

$$\min_{\mathbf{x}, \mathbf{u}} \mathbb{E} \left(\sum_{i=1}^N \sum_{t=0}^T L_{i,t}(\mathbf{x}_{i,t}, \mathbf{u}_{i,t}, \mathbf{w}_t) \right)$$

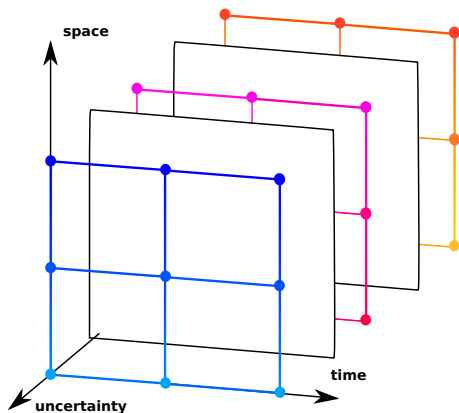

$$\text{s.t. } \mathbf{x}_{i,t+1} = f_{i,t}(\mathbf{x}_{i,t}, \mathbf{u}_{i,t}, \mathbf{w}_t)$$

$$\mathbf{u}_{i,t} = \mathbb{E}(\mathbf{u}_{i,t} \mid \mathbf{w}_0, \dots, \mathbf{w}_t)$$

$$\sum_{i=1}^N \theta_{i,t}(\mathbf{x}_{i,t}, \mathbf{u}_{i,t}, \mathbf{w}_t) = 0$$

[Stochastic Pontryagin]
[Dynamic Programming]

Decomposition/coordination methods: scenario coupling

$$\min_{\mathbf{x}, \mathbf{u}} \mathbb{E} \left(\sum_{i=1}^N \sum_{t=0}^T L_{i,t}(\mathbf{x}_{i,t}, \mathbf{u}_{i,t}, \mathbf{w}_t) \right)$$

$$\text{s.t. } \mathbf{x}_{i,t+1} = f_{i,t}(\mathbf{x}_{i,t}, \mathbf{u}_{i,t}, \mathbf{w}_t)$$

$$\mathbf{u}_{i,t} = \mathbb{E}(\mathbf{u}_{i,t} \mid \mathbf{w}_0, \dots, \mathbf{w}_t)$$

$$\sum_{i=1}^N \theta_{i,t}(\mathbf{x}_{i,t}, \mathbf{u}_{i,t}, \mathbf{w}_t) = 0$$

Decomposition/coordination methods: space coupling

$$\min_{\mathbf{x}, \mathbf{u}} \mathbb{E} \left(\sum_{i=1}^N \sum_{t=0}^T L_{i,t}(\mathbf{x}_{i,t}, \mathbf{u}_{i,t}, \mathbf{w}_t) \right)$$

$$\text{s.t. } \mathbf{x}_{i,t+1} = f_{i,t}(\mathbf{x}_{i,t}, \mathbf{u}_{i,t}, \mathbf{w}_t)$$

$$\sigma(\mathbf{u}_{i,t}) \subset \sigma(\mathbf{w}_0, \dots, \mathbf{w}_t)$$

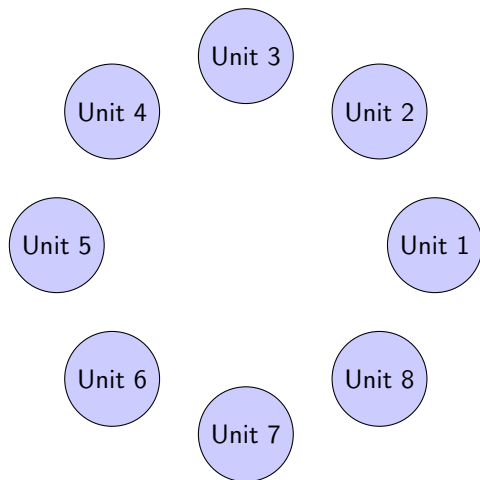

$$\sum_{i=1}^N \theta_{i,t}(\mathbf{x}_{i,t}, \mathbf{u}_{i,t}, \mathbf{w}_t) = 0$$

[Our purpose now]

We have a nice decomposed problem but...

Flower structure

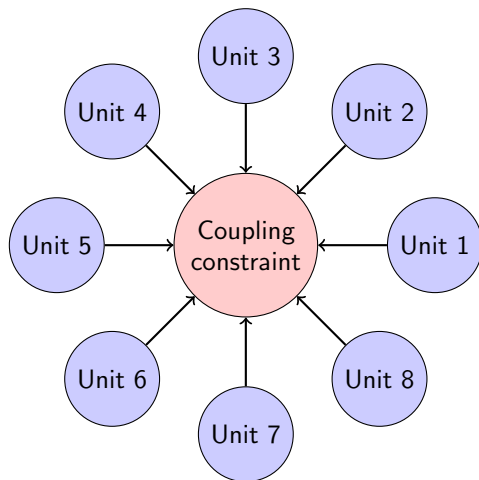

We are almost in the case where units could be driven independently one from another

We have a nice decomposed problem but...

Flower structure

Unfortunately...

The associated optimization problem can be written as

$$\underbrace{\min_{(u_1, \dots, u_N)} \sum_{i=1}^N J_i(u_i)}_{\text{costs minimization}} \quad \text{under} \quad \underbrace{\sum_{i=1}^N \Theta_i(u_i) = D}_{\text{supply = demand}}$$

where

- u_i is the **decision** of each unit i
- $J_i(u_i)$ is the **cost** of making decision u_i for unit i
- $\Theta_i(u_i)$ is the **production** induced by making decision u_i for unit i

Under appropriate duality assumptions,
the associated optimization problem
can be written without constraints

- For a proper Lagrange multiplier λ

$$\min_{(u_1, \dots, u_N)} \sum_{i=1}^N J_i(u_i) + \lambda \underbrace{\left(\sum_{i=1}^N \Theta_i(u_i) - D \right)}_{\text{constraint}}$$

- We distribute the coupling constraint to each unit i

$$\min_{(u_1, \dots, u_N)} \left(\sum_{i=1}^N J_i(u_i) + \lambda \Theta_i(u_i) \right) - \lambda D$$

- The problems splits into N optimization problems

$$\min_{u_i} (J_i(u_i) + \lambda \Theta_i(u_i)), \quad \forall i = 1, \dots, N$$

Proper prices allow decentralization of the optimum

$$\min_{(u_1, \dots, u_N)} \sum_{i=1}^N J_i(u_i) \quad \text{under} \quad \sum_{i=1}^N \Theta_i(u_i) = D$$

The simplest **decomposition/coordination scheme** consists in

- buying the production of each unit at a **price** $\lambda^{(k)}$ at iteration k
- and letting each unit minimize its modified costs

$$\min_{u_i} J_i(u_i) + \underbrace{\lambda^{(k)}}_{\text{price}} \Theta_i(u_i)$$

- then, updating the price depending on the coupling constraint

$$\lambda^{(k+1)} = \lambda^{(k)} + \rho \left(\sum_{i=1}^N \Theta_i(u_i) - D \right)$$

(like in the “tâtonnement de Walras” in Economics)

What are the stakes if we extend spatial coupling constraint decomposition to the dynamical and stochastic setting?

- Allowing for time and uncertainties, we classically consider the criterion

$$\min_{\{\mathbf{u}_{i,t}\}_{i \in \{1,N\}}^{t \in \{0,T-1\}}} \mathbb{E} \left(\sum_{i=1}^N \left(\sum_{t=0}^{T-1} L_{i,t}(\mathbf{x}_{i,t}, \mathbf{u}_{i,t}, \mathbf{w}_{i,t}) + K_i(\mathbf{x}_{i,T}) \right) \right)$$

- under the constraints

$$\sum_{i=1}^N \Theta_{i,t}(\mathbf{x}_{i,t}, \mathbf{u}_{i,t}, \mathbf{w}_{i,t}) - \mathbf{d}_t = 0, \quad t \in \llbracket 0, T-1 \rrbracket$$

$$\mathbf{x}_{i,t+1} = f_{i,t}(\mathbf{x}_{i,t}, \mathbf{u}_{i,t}, \mathbf{w}_{i,t}), \quad i \in \llbracket 1, N \rrbracket, t \in \llbracket 0, T-1 \rrbracket$$

To avoid finding “magical solutions”,
only implementable by a wizard knowing the future,
we need to specify information constraints

- The optimization problem is **not well posed**, because we have not specified upon what depends the control $\mathbf{u}_{i,t}$ of each unit i at each time t
- In the **causal and perfect memory case**, we express that the control $\mathbf{u}_{i,t}$ depends of all past noises up to time t
 - either by a **functional approach**

$$\mathbf{u}_{i,t} = \phi_{i,t}(\mathbf{w}_{1,0}, \dots, \mathbf{w}_{N,0}, \mathbf{d}_0 \dots \dots \mathbf{w}_{1,t}, \dots, \mathbf{w}_{N,t}, \mathbf{d}_t)$$

- or by an **algebraic approach**

$$\sigma(\mathbf{u}_{i,t}) \subset \sigma(\mathbf{w}_{1,0}, \dots, \mathbf{w}_{N,0}, \mathbf{d}_0 \dots \dots \mathbf{w}_{1,t}, \dots, \mathbf{w}_{N,t}, \mathbf{d}_t)$$

Looking after decentralizing prices models

- Going on with the previous scheme, each unit i solves

$$\min_{\mathbf{u}_{i,0}, \dots, \mathbf{u}_{i,T-1}} \mathbb{E} \left(\sum_{t=0}^{T-1} \left(L_{i,t}(\mathbf{x}_{i,t}, \mathbf{u}_{i,t}, \mathbf{w}_{i,t}) + \underbrace{\lambda_{i,t}^{(k)}}_{\text{price}} \Theta_{i,t}(\mathbf{x}_{i,t}, \mathbf{u}_{i,t}, \mathbf{w}_{i,t}) \right) + K_i(\mathbf{x}_{i,T}) \right)$$

$$\mathbf{x}_{i,t+1} = f_{i,t}(\mathbf{x}_{i,t}, \mathbf{u}_{i,t}, \mathbf{w}_{i,t}), \quad t \in \llbracket 0, T-1 \rrbracket$$

- The optimal controls $\mathbf{u}_{i,t}^*$ of this problem depend
 - upon the local state $\mathbf{x}_{i,t}$
 - and ... upon **all past prices** $(\lambda_{i,0}^{(k)}, \dots, \lambda_{i,t}^{(k)})$!
- **Research axis:** find an approximate **dynamical model for the price process**, driven by proper information; for instance, replace $\lambda_{i,t}^{(k)}$ by $\mathbb{E} \left(\lambda_{i,t}^{(k)} \mid \mathbf{y}_t \right)$, where the information variable \mathbf{y}_t is a Markov process (short time memory) → “demand response”, “adaptive tariffs”,

Dual Approximate Dynamic Programming

Extension to interconnected dams

Contribution to dynamic tariffs

- Spatial decomposition of a dynamic stochastic optimization problem
- Lagrange multipliers attached to spatial coupling constraints are stochastic processes (prices)
- By projecting these prices, one expects to identify approximate dynamic models
- Such prices dynamic models are interpreted as dynamic tariffs

Outline of the presentation

 - Ecole des Ponts ParisTech–Cermics–Optimization and Systems
 - Industry partners of the Optimization and Systems Group
- 2 The remolding of power systems seen from an optimizer perspective
 - The remolding of power systems
 - Optimization is challenged
- 3 Moving from deterministic to stochastic dynamic optimization
 - Working out a toy example
 - Expliciting risk attitudes
 - Handling online information
 - Discussing framing and resolution methods
- 4 Two snapshots on ongoing research
 - Decomposition-coordination optimization methods under uncertainty
 - Risk constraints in optimization
- 5 A need for training and research

Tourism issues impose constraints upon traditional economic management of a hydro-electric dam

- Maximizing the revenue from turbinated water
- under a tourism constraint of having enough water in July and August

We consider a single dam nonlinear dynamical model in the decision-hazard setting

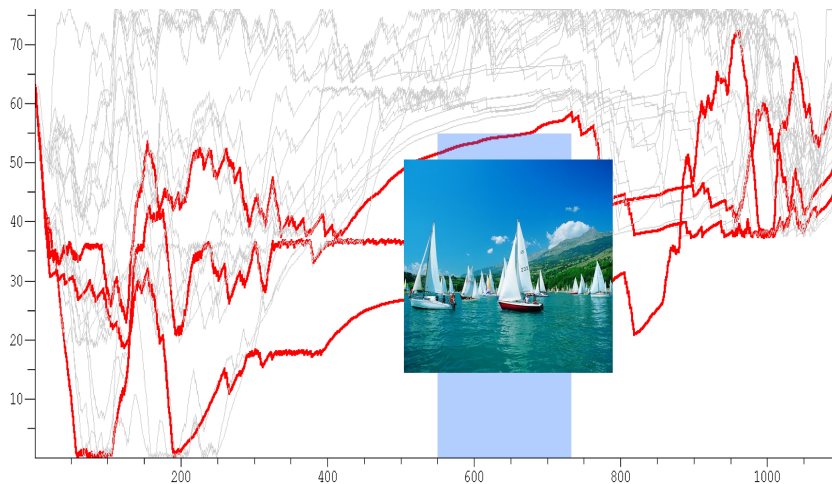

We model the dynamics of the water volume in a dam by

$$\underbrace{S(t+1)}_{\text{future volume}} = \min\left\{ S^\#, \underbrace{S(t)}_{\text{volume}} - \underbrace{q(t)}_{\text{turbined}} + \underbrace{a(t)}_{\text{inflow volume}} \right\}$$

- $S(t)$ **volume** (stock) of water at the beginning of period $[t, t + 1[$
- $q(t)$ **turbined outflow volume** during $[t, t + 1[$
 - decided at the beginning of period $[t, t + 1[$
 - chosen such that $0 \leq q(t) \leq \min\{S(t), q^\#\}$
- $a(t)$ **inflow water volume** (rain, etc.) during $[t, t + 1[$, which materializes at the end $t + 1$ of period $[t, t + 1[$
- $S^\#$ **dam capacity**

The setting is called **decision-hazard** because the **decision** $q(t)$ is made **before** the **hazard** $a(t)$

The red stock trajectories fail to meet the tourism constraint in July and August

In the risk-neutral economic approach, an optimal management maximizes the expected payoff

- Suppose that
 - **turbined water** $q(t)$ is sold at price $p(t)$,
related to the price at which energy can be sold at time t
 - a **probability** \mathbb{P} is given on the set $\Omega = \mathbb{R}^{T-t_0} \times \mathbb{R}^{T-t_0}$
of **water inflows scenarios** $(a(t_0), \dots, a(T-1))$
and **prices scenarios** $(p(t_0), \dots, p(T-1))$
 - at the horizon, the **final volume** $S(T)$ has a value $K(S(T))$,
the “final value of water”
- The traditional (risk-neutral) economic problem is to maximize the intertemporal payoff (without discounting if the horizon is short)

$$\max \mathbb{E} \left[\sum_{t=t_0}^{T-1} \left(\underbrace{p(t)}_{\text{price}} \underbrace{q(t)}_{\text{turbined}} - \underbrace{\epsilon q(t)^2}_{\text{turbined costs}} \right) + \underbrace{K(S(T))}_{\text{final volume utility}} \right]$$

We now have a stochastic optimization problem,
where the tourism constraint still needs
to be dressed in formal clothes

- Traditional cost minimization/payoff maximization

$$\max \mathbb{E} \left[\sum_{t=t_0}^{T-1} \overbrace{p(t)q(t) - \epsilon q(t)^2}^{\text{turbined water payoff}} + \overbrace{K(S(T))}^{\text{final volume utility}} \right]$$

- Tourism constraint

$$\text{volume } S(t) \geq S^b, \quad \forall t \in \mathcal{T} = \{\text{July, August}\}$$

- In what sense should we consider this inequality
which involves the **random variables** $S(t)$ for $t \in \mathcal{T}$?

Robust / almost sure / probability constraint

- **Robust** constraints: for all the scenarios in a subset $\bar{\Omega} \subset \Omega$

$$S(t) \geq s^b, \forall t \in \mathcal{T}$$

- **Almost sure** constraints

$$\text{Probability} \left\{ S(t) \geq s^b, \forall t \in \mathcal{T} \right\} = 1$$

- **Probability** constraints, with “confidence” level $p \in [0, 1]$

$$\text{Probability} \left\{ S(t) \geq s^b, \forall t \in \mathcal{T} \right\} \geq p$$

- and also by penalization, or in the mean, etc.

Our problem may be clothed as a stochastic optimization problem under a probability constraint

$$P(T) = \sum_{t=t_0}^{T-1} \overbrace{p(t)q(t) - \epsilon q(t)^2}^{\text{turbined water payoff}} + \overbrace{K(S(T))}^{\text{final volume utility}}$$

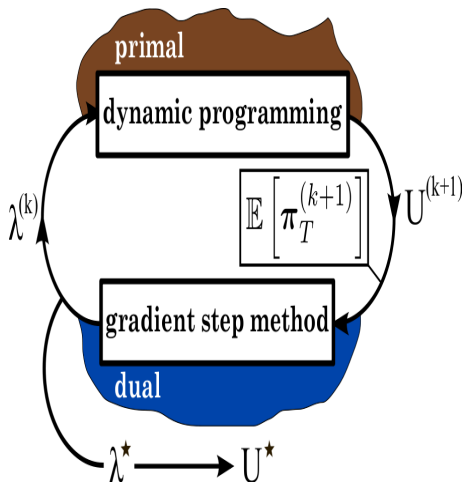

- The traditional economic problem is $\max \mathbb{E}[P(T)]$
- and a failure tolerance is accepted

$$\text{Probability} \left\{ S(t) \geq S^b, \forall t \in \mathcal{T} \right\} \geq 90\%$$

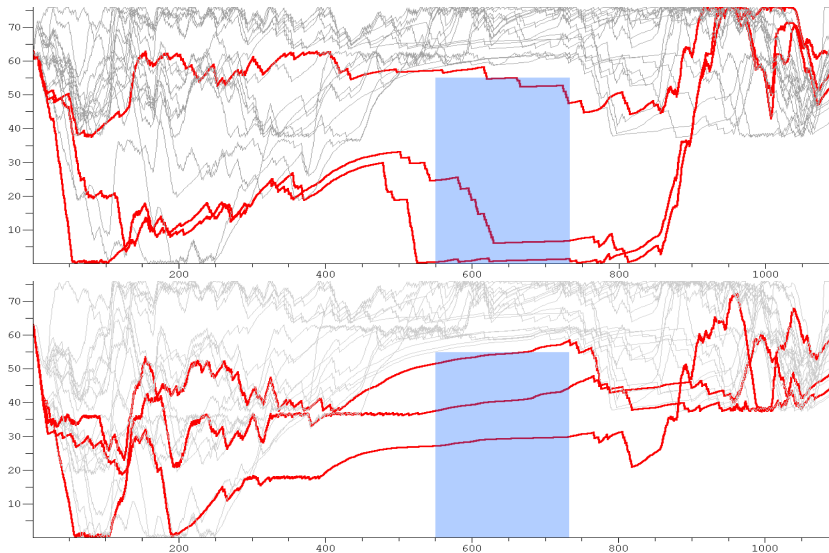

- Details concerning the theoretical and numerical resolution are available on demand ;-)

Details concerning the theoretical and numerical resolution are available on demand ;-)

- $\pi(0) = 1$ and $\pi(t+1) = \begin{cases} \mathbf{1}_{\{S(t+1) \geq S^b\}} \times \pi(t) & \text{if } t \in \mathcal{T} \\ \pi(t) & \text{else} \end{cases}$
- $\mathbb{P}[S(\tau) \geq S^b, \forall \tau \in \mathcal{T}] = \mathbb{E}[\mathbf{1}_{\{S(\tau) \geq S^b, \forall \tau \in \mathcal{T}\}}] = \mathbb{E}[\prod_{\tau \in \mathcal{T}} \mathbf{1}_{\{S(\tau) \geq S^b\}}] = \mathbb{E}[\pi(T)]$

90% of the stock trajectories meet the tourism constraint

Our resolution approach brings a sensible improvement compared to standard procedures

OPTIMAL POLICIES	OPTIMIZATION		SIMULATION		
	Iterations	Time	Gain	Respect	Well behaviour
Standard	15	10 mn	ref	0,9	no
Convenient	10	160 mn	-3.20%	0,9	yes
Heuristic	10	160 mn	-3.25%	0,9	yes

However, though the expected payoff is optimal, the payoff effectively realized can be far from it

We propose a stochastic viability formulation to treat symmetrically and to guarantee both environmental and economic objectives

- Given two thresholds to be guaranteed
 - a volume S^b (measured in cubic hectometers hm^3)
 - a payoff P^b (measured in numeraire \$)
- we look after policies achieving the **maximal viability probability**

$$\Pi(S^b, P^b) = \max \text{Proba} \left\{ \begin{array}{l} \text{water inflow scenarios along which} \\ \text{the volumes } S(t) \geq S^b \\ \text{for all time } t \in \{ \text{July, August} \} \\ \text{and the final payoff } P(T) \geq P^b \end{array} \right\}$$

- $\Pi(S^b, P^b)$ is the **maximal probability** to guarantee to be above the thresholds S^b and P^b

The stochastic viability formulation requires to redefine state and dynamics

- The state is the couple $x(t) = (S(t), P(t))$ volume/payoff
- The control $u(t) = q(t)$ is the turbined water
- The dynamics is

$$\underbrace{S(t+1)}_{\text{future volume}} = \min \left\{ S^\#, \underbrace{S(t)}_{\text{volume}} - \underbrace{q(t)}_{\text{turbined}} + \underbrace{a(t)}_{\text{inflow volume}} \right\},$$

$$t = t_0, \dots, T-1$$

$$\underbrace{P(t+1)}_{\text{future payoff}} = \underbrace{P(t)}_{\text{payoff}} + \underbrace{p(t)q(t) - \epsilon q(t)^2}_{\text{turbined water payoff}}, \quad t = t_0, \dots, T-2$$

$$P(T) = P(T-1) + \underbrace{K(S(T))}_{\text{final volume utility}}$$

In the stochastic viability formulation, we dress objectives as state constraints

- The control constraints are

$$u(t) \in \mathbb{B}(t, x(t)) \iff 0 \leq q(t) \leq \min\{S(t), q^\#\}$$

- The state constraints are

$$x(t) \in \mathbb{A}(t) \iff \begin{cases} S(t) \geq S^b \\ P(T) \geq P^b \end{cases}, \quad \forall t \in \{\text{July, August}\}$$

For each couple of thresholds on payoff and stock, we write a dynamic programming equation

- Abstract version

$$\begin{aligned} V(T, x) &= \mathbf{1}_{A(T)}(x) \\ V(t, x) &= \mathbf{1}_{A(t)}(x) \max_{u \in \mathbb{B}(t, x)} \mathbb{E}_{w(t)} \left[V(t+1, \text{Dyn}(t, x, u, w(t))) \right] \end{aligned}$$

- Specific version

$$V(T, S, P) = \mathbf{1}_{\{P \geq P^b\}}$$

$$V(T-1, S, P) = \max_{0 \leq q \leq \min\{S, q^\#\}} \mathbb{E}_{a(T-1), p(T-1)} \left[V(t+1, S - q + a(t), P + K(S)) \right]$$

$$V(t, S, P) = \max_{0 \leq q \leq \min\{S, q^\#\}} \mathbb{E}_{a(t), p(t)} \left[V(t+1, S - q + a(t), P + p(t)q - \epsilon q^2) \right], \\ t \notin \{ \text{July, August} \}$$

$$V(t, S, P) = \mathbf{1}_{\{S \geq S^b\}} \max_{0 \leq q \leq \min\{S, q^\#\}} \mathbb{E}_{a(t), p(t)} \left[V(t+1, S - q + a(t), P + p(t)q - \epsilon q^2) \right], \\ t \in \{ \text{July, August} \}$$

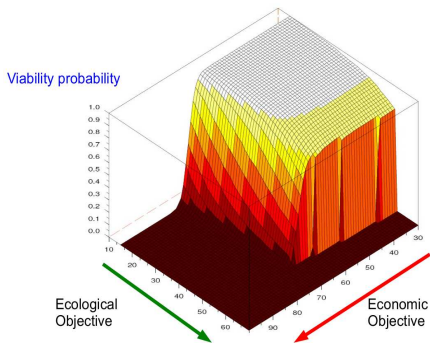

We plot iso-values for the maximal viability probability as a function of guaranteed thresholds S^b and P^b

The probability distribution of the random gain reflects the viability objectives

Contribution to quantitative sustainable management

- Conceptual framework for quantitative sustainable management
- Managing ecological and economic conflicting objectives
- Displaying tradeoffs between ecology and economy sustainability thresholds and risk

Outline of the presentation

- 1 Long term industry-academy cooperation
- 2 The remolding of power systems seen from an optimizer perspective
- 3 Moving from deterministic to stochastic dynamic optimization
- 4 Two snapshots on ongoing research
- 5 A need for training and research**

Trends are favorable to statistics and optimization

- More telecom technology
 ⇨ more data
- More data, more unpredictability
 ⇨ more statistics
- More unpredictability
 ⇨ more storage
 ⇨ more dynamic optimization
- More unpredictability
 ⇨ more stochastic dynamic optimization

A context of increasing complexity

● Multiple levels of integration – interoperability
● Distributed Generation ● Renewable Generation ● Storage ● Demand Response

- Multiple energy resources: photovoltaic, solar heating, heatpumps, wind, hydraulic power, combined heat and power
- Spatially distributed energy resources (onshore and offshore windpower, solarfarms), producers, consumers
- Strongly variable production: wind, solar
- Intermittent demand: electrical vehicles
- Two-ways flows in the electrical network
- Environmental and risk constraints (CO₂, nuclear risk, land use)

Challenges ahead for stochastic optimization

- large scale stochastic optimization
- various risk constraints
- decentralized and private information
- game theory, stochastic equilibrium, market design...
