# Variance reduction approaches in stochastic homogenization 

## Frédéric Legoll

ENPC (Navier) and INRIA (MICMAC team-project)

Joint work with William Minvielle (ENPC and INRIA)

CEMRACS 2013 seminar
August 7, 2013

## Setting

Homogenization of random materials often leads to very expensive computations, and thus many practical difficulties.

Simplify the situation from the theoretical viewpoint: consider the simple scalar linear PDE

$$
-\operatorname{div}\left[A\left(\frac{x}{\varepsilon}, \omega\right) \nabla u^{\varepsilon}\right]=f \quad \text { in some domain } \mathcal{D}, \quad u^{\varepsilon}=0 \text { on } \partial \mathcal{D} .
$$

Thermal diffusion, ...

## Outline of the talk

- Some background materials on random homogenization
- Variance reduction by the control variate approach
- A weakly stochastic model (rare defects) due to A. Anantharaman and C. Le Bris
- Use this model to build a surrogate model and design a control variate approach to reduce the variance

## Random homogenization

## Homogenization 1.0.1: the periodic setting

$$
-\operatorname{div}\left[A_{\mathrm{per}}\left(\frac{x}{\varepsilon}\right) \nabla u^{\varepsilon}\right]=f \text { in } \mathcal{D}, \quad u^{\varepsilon}=0 \text { on } \partial \mathcal{D}, \quad A_{\mathrm{per}} \text { is } \mathbb{Z}^{d} \text {-periodic. }
$$

## Homogenization 1.0.1: the periodic setting

$$
-\operatorname{div}\left[A_{\text {per }}\left(\frac{x}{\varepsilon}\right) \nabla u^{\varepsilon}\right]=f \text { in } \mathcal{D}, \quad u^{\varepsilon}=0 \text { on } \partial \mathcal{D}, \quad A_{\text {per }} \text { is } \mathbb{Z}^{d} \text {-periodic. }
$$

When $\varepsilon \rightarrow 0, u^{\varepsilon}$ converges to $u^{\star}$ solution to

$$
-\operatorname{div}\left[A^{\star} \nabla u^{\star}\right]=f \text { in } \mathcal{D}, \quad u^{\star}=0 \text { on } \partial \mathcal{D} .
$$

The effective matrix $A^{\star}$ is given by

$$
\left[A^{\star}\right]_{i j}=\int_{Q} e_{i}^{T} A_{\mathrm{per}}(y)\left(e_{j}+\nabla w_{e_{j}}(y)\right) d y, \quad Q=\text { unit cube }=(0,1)^{d},
$$

where, for any $p \in \mathbb{R}^{d}$, $w_{p}$ solves the so-called corrector problem:

$$
-\operatorname{div}\left[A_{\mathrm{per}}(y)\left(p+\nabla w_{p}\right)\right]=0, \quad w_{p} \text { is } \mathbb{Z}^{d} \text {-periodic. }
$$

## Homogenization 1.0.1: the periodic setting

$$
-\operatorname{div}\left[A_{\text {per }}\left(\frac{x}{\varepsilon}\right) \nabla u^{\varepsilon}\right]=f \text { in } \mathcal{D}, \quad u^{\varepsilon}=0 \text { on } \partial \mathcal{D}, \quad A_{\text {per }} \text { is } \mathbb{Z}^{d} \text {-periodic. }
$$

When $\varepsilon \rightarrow 0, u^{\varepsilon}$ converges to $u^{\star}$ solution to

$$
-\operatorname{div}\left[A^{\star} \nabla u^{\star}\right]=f \text { in } \mathcal{D}, \quad u^{\star}=0 \text { on } \partial \mathcal{D} .
$$

The effective matrix $A^{\star}$ is given by

$$
\left[A^{\star}\right]_{i j}=\int_{Q} e_{i}^{T} A_{\mathrm{per}}(y)\left(e_{j}+\nabla w_{e_{j}}(y)\right) d y, \quad Q=\text { unit cube }=(0,1)^{d},
$$

where, for any $p \in \mathbb{R}^{d}$, $w_{p}$ solves the so-called corrector problem:

$$
-\operatorname{div}\left[A_{\mathrm{per}}(y)\left(p+\nabla w_{p}\right)\right]=0, \quad w_{p} \text { is } \mathbb{Z}^{d} \text {-periodic. }
$$

$\rightarrow$ The corrector problem is set on the bounded domain $Q$ : easy!

## Stochastic homogenization: setting

We consider statistically homogeneous random materials:

$$
-\operatorname{div}\left[A\left(\frac{x}{\varepsilon}, \omega\right) \nabla u^{\varepsilon}\right]=f \quad \text { in } \quad \mathcal{D}
$$

The tensor $A(x, \omega)$ is such that, for any $k \in \mathbb{Z}^{d}$,

$$
A(x, \omega) \text { and } A(x+k, \omega) \text { share the same probability distribution. }
$$

For a given realization of the randomness, properties may be different. But, on average, they are identical: the material is statistically homogeneous (and $\mathbb{E}[A(x, \cdot)]$ is $\mathbb{Z}^{d}$ periodic).

There is some order in the randomness.

## Averaging theorems

- Periodic case: for any $F_{\text {per }} \in L^{\infty}\left(\mathbb{R}^{d}\right)$ that is $\mathbb{Z}^{d}$-periodic,

$$
F_{\mathrm{per}}\left(\frac{x}{\varepsilon}\right) \underset{\varepsilon \rightarrow 0}{\stackrel{*}{\longrightarrow}} \int_{Q} F_{\mathrm{per}}(y) d y \quad \text { in } L^{\infty}\left(\mathbb{R}^{d}\right), \quad Q=(0,1)^{d}
$$

- Stochastic case: for any $F \in L^{\infty}\left(\mathbb{R}^{d}, L^{1}(\Omega)\right)$ that is statistically homogeneous (i.e. random ergodic stationary),

$$
F\left(\frac{x}{\varepsilon}, \omega\right) \underset{\varepsilon \rightarrow 0}{*} \mathbb{E}\left(\int_{Q} F(y, \cdot) d y\right) \quad \text { in } L^{\infty}\left(\mathbb{R}^{d}\right), \text { almost surely. }
$$

## Stochastic homogenization: result

$-\operatorname{div}\left[A\left(\frac{x}{\varepsilon}, \omega\right) \nabla u^{\varepsilon}\right]=f \quad$ in $\mathcal{D}, \quad u^{\varepsilon}=0$ on $\partial \mathcal{D}, \quad A$ stat. homog.
$u^{\varepsilon}(\cdot, \omega)$ converges (a.s.) to $u^{\star}$ solution to

$$
-\operatorname{div}\left[A^{\star} \nabla u^{\star}\right]=f \quad \text { in } \quad \mathcal{D}, \quad u^{\star}=0 \text { on } \partial \mathcal{D},
$$

## Stochastic homogenization: result

$$
-\operatorname{div}\left[A\left(\frac{x}{\varepsilon}, \omega\right) \nabla u^{\varepsilon}\right]=f \quad \text { in } \mathcal{D}, \quad u^{\varepsilon}=0 \text { on } \partial \mathcal{D}, \quad A \text { stat. homog. }
$$

$u^{\varepsilon}(\cdot, \omega)$ converges (a.s.) to $u^{\star}$ solution to

$$
-\operatorname{div}\left[A^{\star} \nabla u^{\star}\right]=f \quad \text { in } \quad \mathcal{D}, \quad u^{\star}=0 \text { on } \partial \mathcal{D},
$$

where the homogenized matrix $A^{\star}$ is given by

$$
\begin{gathered}
{\left[A^{\star}\right]_{i j}=\mathbb{E}\left(\int_{Q} e_{i}^{T} A(y, \cdot)\left(e_{j}+\nabla w_{e_{j}}(y, \cdot)\right) d y\right),} \\
\left\{\begin{array}{l}
-\operatorname{div}\left[A(y, \omega)\left(p+\nabla w_{p}(y, \omega)\right)\right]=0 \quad \text { in } \quad \mathbb{R}^{d}, \quad p \in \mathbb{R}^{d}, \\
\nabla w_{p} \text { is stat. homog., } \mathbb{E}\left(\int_{Q} \nabla w_{p}(y, \cdot) d y\right)=0 .
\end{array}\right.
\end{gathered}
$$

In contrast to the periodic case, the corrector problem is set on $\mathbb{R}^{d}$.

## Standard discretization

- Solve the corrector problem on a truncated domain:

$$
\left\{\begin{array}{l}
-\operatorname{div}\left[A(y, \omega)\left(p+\nabla w_{p}^{N}(y, \omega)\right)\right]=0 \\
w_{p}^{N} \quad \text { is } Q_{N} \text {-periodic, } \quad Q_{N}=(-N, N)^{d}
\end{array}\right.
$$

- This yields an approximate (apparent) homogenized matrix

$$
\left[A_{N}^{\star}\right]_{i j}(\omega)=\frac{1}{\left|Q_{N}\right|} \int_{Q_{N}} e_{i}^{T} A(y, \omega)\left(e_{j}+\nabla w_{e_{j}}^{N}(y, \omega)\right) d y
$$

Due to numerical truncation, $A_{N}^{\star}$ is random!

- Bourgeat \& Piatnitski, 2004:

$$
\lim _{N \rightarrow \infty} A_{N}^{\star}(\omega) \rightarrow A^{\star} \quad \text { a.s. }
$$

## An academic random material

$A(x, \omega)=\sum_{k \in \mathbb{Z}^{2}} 1_{Q+k}(x) a_{k}(\omega) \operatorname{ld}_{2}, \quad a_{k}$ independent identically distributed
$a_{k}=\alpha$ or $\beta$ with equal probability.

## Monte Carlo approximation

- Consider $M$ independent realizations $A^{m}(y, \omega)$, compute for each
- the corrector $w_{p}^{N, m}$ on $Q_{N}$ :

$$
-\operatorname{div}\left[A^{m}(y, \omega)\left(p+\nabla w_{p}^{N, m}(y, \omega)\right)\right]=0, \quad w_{p}^{N, m} \text { is } Q_{N} \text {-periodic, }
$$

- and the approximate homogenized matrix $A_{N, m}^{\star}(\omega)$.
- Approximate $\mathbb{E}\left(A_{N}^{\star}\right)$ by $I_{M}=\frac{1}{M} \sum_{m=1}^{M} A_{N, m}^{\star}(\omega)$.

## Monte Carlo approximation

- Consider $M$ independent realizations $A^{m}(y, \omega)$, compute for each
- the corrector $w_{p}^{N, m}$ on $Q_{N}$ :

$$
-\operatorname{div}\left[A^{m}(y, \omega)\left(p+\nabla w_{p}^{N, m}(y, \omega)\right)\right]=0, \quad w_{p}^{N, m} \text { is } Q_{N} \text {-periodic, }
$$

- and the approximate homogenized matrix $A_{N, m}^{\star}(\omega)$.
- Approximate $\mathbb{E}\left(A_{N}^{\star}\right)$ by $\quad I_{M}=\frac{1}{M} \sum_{m=1}^{M} A_{N, m}^{\star}(\omega)$.

Classical confidence interval: with a probability equal to 95 \%,

$$
\left|\mathbb{E}\left(\left[A_{N}^{\star}\right]_{i j}\right)-\left[I_{M}\right]_{i j}\right| \leq 1.96 \frac{\sqrt{\operatorname{Var}\left(\left[A_{N}^{\star}\right]_{i j}\right)}}{\sqrt{M}}
$$

## In practice, on a typical example

$I_{M} \approx \mathbb{E}\left(\left[A_{N}^{\star}\right]_{11}\right)$ (along with confidence intervals) for a given number $M$ of realizations, and several sizes for $Q_{N}$.

## Objective

$$
A^{\star}-A_{N}^{\star}(\omega)=\underset{\text { systematic error }}{A^{\star}-\underset{\text { statistical error }}{\mathbb{E}}\left[A_{N}^{\star}\right]}+\underset{\text { stan }}{\mathbb{E}}\left[A_{N}^{\star}\right]-A_{N}^{\star}(\omega)
$$

- several studies on convergence rates wrt $N$ :
- Yurinskii 1986, Bourgeat \& Piatniski 2004
- Naddaf \& Spencer 1998
- Gloria \& Otto 2011-13
- this is NOT the question we want to address here.

Our aim: for fixed $N$, compute $\mathbb{E}\left(A_{N}^{\star}\right)$ more efficiently.

- Central Limit Theorem (CLT):

$$
\left|\mathbb{E}\left(\left[A_{N}^{\star}\right]_{i j}\right)-\left[I_{M}\right]_{i j}\right| \leq 1.96 \frac{\sqrt{\operatorname{Var}\left(\left[A_{N}^{\star}\right]_{i j}\right)}}{\sqrt{M}}
$$

- Can we reduce the prefactor in the CLT? For the same $M$ (same cost), get a smaller confidence interval?

## Variance reduction using control variate

Let $X(\omega)$ be a scalar random variable. We want to compute $\mathbb{E}(X)$.

Later, we will take $X(\omega)=\left[A_{N}^{\star}(\omega)\right]_{i j}$ for some $1 \leq i, j \leq d$.

## Estimating $\mathbb{E}(X)$

- standard Monte Carlo method: generate $M$ independent realizations of $X(\omega)$, and approximate $\mathbb{E}(X)$ by
$I_{M}^{\mathrm{MC}}=\frac{1}{M} \sum_{m=1}^{M} X\left(\omega_{m}\right)$ that satisfies $\left|\mathbb{E}(X)-I_{M}^{\mathrm{MC}}\right| \leq 1.96 \frac{\sqrt{\operatorname{Var}(X)}}{\sqrt{M}}$

## Estimating $\mathbb{E}(X)$

- standard Monte Carlo method: generate $M$ independent realizations of $X(\omega)$, and approximate $\mathbb{E}(X)$ by
$I_{M}^{\mathrm{MC}}=\frac{1}{M} \sum_{m=1}^{M} X\left(\omega_{m}\right) \quad$ that satisfies

$$
\left|\mathbb{E}(X)-I_{M}^{\mathrm{MC}}\right| \leq 1.96 \frac{\sqrt{\operatorname{Var}(X)}}{\sqrt{M}}
$$

- control variate method: consider $X_{\text {app }}(\omega)$ a random variable "close" to $X(\omega)$, s.t. $\mathbb{E}\left[X_{\text {app }}\right]$ is analytically computable, and introduce

$$
C(\omega)=X(\omega)-\rho\left(X_{\mathrm{app}}(\omega)-\mathbb{E}\left[X_{\mathrm{app}}\right]\right)
$$

where $\rho$ is a deterministic parameter.
Approximate $\mathbb{E}(X)=\mathbb{E}(C)$ by
$I_{M}^{\mathrm{CV}}=\frac{1}{M} \sum_{m=1}^{M} C\left(\omega_{m}\right)$ that satisfies $\left|\mathbb{E}(X)-I_{M}^{\mathrm{CV}}\right| \leq 1.96 \frac{\sqrt{\operatorname{Var}(C)}}{\sqrt{M}}$

- Accuracy gain iff $\operatorname{Var}(C)<\operatorname{Var}(X)$.

## Choice of the control variate $X_{\text {app }}(\omega)$

$C(\omega)=X(\omega)-\rho\left(X_{\text {app }}(\omega)-\mathbb{E}\left[X_{\text {app }}\right]\right), \quad \rho$ deterministic parameter

$$
I_{M}^{\mathrm{CV}}=\frac{1}{M} \sum_{m=1}^{M} C\left(\omega_{m}\right) \quad \text { satisfies } \quad\left|\mathbb{E}(X)-I_{M}^{\mathrm{CV}}\right| \leq 1.96 \frac{\sqrt{\operatorname{Var}(C)}}{\sqrt{M}}
$$

## Extreme cases:

- $X_{\text {app }}$ is deterministic: then $C(\omega)=X(\omega)$ and no gain!
- $X_{\text {app }}=X$ : for $\rho=1, C$ is deterministic (hence small variance!), but the algorithm requires $\mathbb{E}\left[X_{\text {app }}\right]=\mathbb{E}(X)$, which is what we are looking for! Not practical!

In general, we need something in-between (problem-dependent).

## Choice of the deterministic parameter $\rho$

$C(\omega)=X(\omega)-\rho\left(X_{\text {app }}(\omega)-\mathbb{E}\left[X_{\text {app }}\right]\right), \quad \rho$ deterministic parameter We wish to minimize the variance of $C$.

- For any choice of $X_{\text {app }}(\omega)$, there exists an optimal $\rho$ that minimizes the variance of $C$ :

$$
\rho_{\text {opt }}=\frac{\operatorname{Cov}\left(X, X_{\mathrm{app}}\right)}{\operatorname{Var}\left(X_{\mathrm{app}}\right)}
$$

Not exactly computable in practice, but can be well enough approximated by an empirical mean.

- For this optimal choice of $\rho$,

$$
\frac{\operatorname{Var}(C)}{\operatorname{Var}(X)}=1-\frac{\left(\operatorname{Cov}\left(X, X_{\text {app }}\right)\right)^{2}}{\operatorname{Var}(X) \operatorname{Var}\left(X_{\text {app }}\right)}<1
$$

The more $X$ and $X_{\text {app }}$ are correlated, the better!

## A weakly stochastic case:

## Rare defects in a periodic structure

A. Anantharaman and C. Le Bris,

- C. R. Acad. Sciences 348 (2010)
- SIAM MMS 9 (2011)
- Comm. Comp. Phys. 11 (2012)

Our aim wrt variance reduction: build a surrogate model close to $A_{N}^{\star}(\omega)$.

## A defect model (A. Anantharaman and C. Le Bris, CRAS 2010)

$A_{\text {per }}$ : fiber
$A_{\text {per }}+C_{\text {per }}=\mathrm{ld}:$ no fiber (defect)

$$
A(x, \omega)=A_{\text {per }}(x)+b_{\eta}(x, \omega) C_{\text {per }}(x)
$$

where $A_{\text {per }}$ and $C_{\text {per }}$ are both $\mathbb{Z}^{d}$-periodic, and

$$
b_{\eta}(x, \omega)=\sum_{k \in \mathbb{Z}^{d}} 1_{Q+k}(x) B_{\eta}^{k}(\omega), \quad Q=(0,1)^{d}
$$

where $\left\{B_{\eta}^{k}\right\}_{k \in \mathbb{Z}^{d}}$ are i.i.d. random variables:

$$
\mathbb{P}\left(B_{\eta}^{k}=1\right)=\eta, \quad \mathbb{P}\left(B_{\eta}^{k}=0\right)=1-\eta .
$$

When $\eta$ is a small parameter, $A=A_{\text {per }}$ "most of the time".

## Defects may be not so rare!

| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

Left: perfect (periodic) material: $\eta=0$.
Right: a realization of the material with defects of probability $\eta=0.4$.

When $\eta=1 / 2$, defects are as frequent as non-defects!
A realization of the matrix $A$ on $Q_{N}$ is determined by the collection of the $B_{k}^{\eta}$ (0: fiber; 1: no fiber $=$ defect) in each cell $k$ of $Q_{N}$.

## Genericity of the setting

## 

$$
A(x, \omega)=\sum_{k \in \mathbb{Z}^{2}} 1_{Q+k}(x) a_{k}(\omega) \operatorname{ld}_{2}, \quad \mathbb{P}\left(a_{k}=\alpha\right)=\mathbb{P}\left(a_{k}=\beta\right)=1 / 2
$$

Then $\quad A(x, \omega)=A_{\text {per }}(x)+b_{\eta}(x, \omega) C_{\text {per }}(x)$
with

$$
A_{\text {per }}(x)=\alpha, \quad A_{\text {per }}(x)+C_{\text {per }}(x)=\beta, \quad \eta=1 / 2 .
$$

## Homogenized matrix expansion (Anantharaman Le Bris, CRAS 2010)

- Approximate homogenized matrix:

$$
A_{N}^{\star}(\omega) p=\frac{1}{\left|Q_{N}\right|} \int_{Q_{N}} A(y, \omega)\left(\nabla w_{p}^{N}(y, \omega)+p\right) d y
$$

where we solve the corrector problem on $Q_{N}=(-N, N)^{d}$ :

$$
-\operatorname{div}\left[A(y, \omega)\left(p+\nabla w_{p}^{N}(y, \omega)\right)\right]=0, \quad w_{p}^{N} \text { is } Q_{N} \text {-periodic. }
$$

- By enumerating all possible realizations of $A(x, \omega)$ on $Q_{N}$, we obtain an expansion of $\mathbb{E}\left[A_{N}^{\star}\right]$ in powers of $\eta$ :
$\mathbb{E}\left[A_{N}^{\star}\right]=\sum A_{N}^{\star}(\omega) \mathbb{P}(\omega)+\quad \sum \quad A_{N}^{\star}(\omega) \mathbb{P}(\omega)+\ldots$

$$
\begin{aligned}
& \omega \text { s.t. } 0 \text { defect } \\
= & (1-\eta)^{N^{d}} A_{\mathrm{per}}^{\star}+\sum_{k \in I_{N}} \eta(1-\eta)^{N^{d}-1} A_{N}^{\star}(1 \text { defect in } k)+\ldots \\
= & A_{\mathrm{per}}^{\star}+\eta \bar{A}_{1}^{\star, N}+\eta^{2} \bar{A}_{2}^{\star, N}+O\left(\eta^{3}\right)
\end{aligned}
$$

$$
\mathbb{E}\left[A_{N}^{*}\right]=A_{\text {per }}^{*}+\eta \bar{A}_{1}^{*, N}+\eta^{2} \bar{A}_{2}^{*, N}
$$

Leading order term given by the periodic (no defect!) situation:

$$
-\operatorname{div}\left[A_{\mathrm{per}}\left(p+\nabla w_{p}^{0}\right)\right]=0, \quad w_{p}^{0} \text { is } Q \text {-periodic }
$$

and

$$
A_{\mathrm{per}}^{\star} p=\int_{Q} A_{\mathrm{per}}\left(\nabla w_{p}^{0}+p\right) .
$$

## $\mathbb{E}\left[A_{N}^{*}\right]=A_{\text {per }}^{*}+\eta \bar{A}_{1}^{*, N}+\eta^{2} \bar{A}_{2}^{*, N}$

$$
\begin{aligned}
\bar{A}_{1}^{\star, N} p & =\frac{1}{\left|Q_{N}\right|} \sum_{k \in I_{N}}\left[\int_{Q_{N}} A_{1}^{k}\left(\nabla w_{p}^{1, k}+p\right)-\int_{Q_{N}} A_{\mathrm{per}}\left(\nabla w_{p}^{0}+p\right)\right] \\
& =\frac{1}{\left|Q_{N}\right|} \sum_{k \in I_{N}} \mathcal{A}_{k}^{1} \operatorname{def} p
\end{aligned}
$$

where $w_{p}^{0}$ is the periodic corrector (no defect) and $w_{p}^{1, k}$ is the corrector associated to

$$
\left.A_{1}^{k}=A_{\mathrm{per}}+\mathbf{1}_{Q+k} C_{\text {per }} \quad \text { (material with a single defect in } Q+k\right)
$$

$$
-\operatorname{div}\left[A_{1}^{k}\left(p+\nabla w_{p}^{1, k}\right)\right]=0
$$

$w_{p}^{1, k}$ is $Q_{N}$-periodic.
Remark: here, due to periodic BC, $\mathcal{A}_{k}^{1 \text { def }}$ independent of $k$.

## $\mathbb{E}\left[A_{N}^{\star}\right]=A_{\text {per }}^{\star}+\eta \bar{A}_{1}^{*, N}+\eta^{2} \bar{A}_{2}^{\star, N}+\cdots$

$$
\bar{A}_{1}^{\star, N} p=\frac{1}{\left|Q_{N}\right|} \sum_{k \in I_{N}} \mathcal{A}_{k}^{1 \operatorname{def}} p
$$

where $\mathcal{A}_{k}^{1 \text { def }}$ is the marginal contribution of a single defect in $k$.

## $\mathbb{E}\left[A_{N}^{*}\right]=A_{\text {per }}^{*}+\eta \bar{A}_{1}^{*, N}+\eta^{2} \bar{A}_{2}^{*, N}$

$$
\bar{A}_{1}^{\star, N} p=\frac{1}{\left|Q_{N}\right|} \sum_{k \in I_{N}} \mathcal{A}_{k}^{1 \operatorname{def}} p
$$

where $\mathcal{A}_{k}^{1 \text { def }}$ is the marginal contribution of a single defect in $k$.

Similar expression for second order:

$$
\bar{A}_{2}^{\star, N} p=\frac{1}{2\left|Q_{N}\right|} \sum_{k \neq \ell} \mathcal{A}_{k, \ell}^{2 \text { def }} p
$$

Marginal contribution from pairs of defects.

## $\mathbb{E}\left[A_{N}^{*}\right]=A_{\text {per }}^{*}+\eta \bar{A}_{1}^{*, N}+\eta^{2} \bar{A}_{2}^{*, N}$

$$
{\overline{A_{1}}}^{\star, N} p=\frac{1}{\left|Q_{N}\right|} \sum_{k \in I_{N}} \mathcal{A}_{k}^{1 \operatorname{def}} p
$$

where $\mathcal{A}_{k}^{1 \text { def }}$ is the marginal contribution of a single defect in $k$.

Similar expression for second order:

$$
\bar{A}_{2}^{\star, N} p=\frac{1}{2\left|Q_{N}\right|} \sum_{k \neq \ell} \mathcal{A}_{k, \ell}^{2 \text { def }} p
$$

Marginal contribution from
pairs of defects.

Possible to use a Reduced Basis approach to compute $w_{p}^{2, k, \ell}$, corrector associated to $A_{2}^{k, \ell}=A_{\text {per }}+\mathbf{1}_{Q+k} C_{\text {per }}+\mathbf{1}_{Q+\ell} C_{\text {per }}$.
C. Le Bris and F. Thomines, CAM 2012.

## A control variate approach

Joint work with W. Minvielle.

Our aim: at any given $N$, compute $\mathbb{E}\left(A_{N}^{\star}\right)$ more efficiently.

## Control variate - 1

$$
\mathbb{E}\left[A_{N}^{\star}\right]=A_{\mathrm{per}}^{\star}+\eta \bar{A}_{1}^{\star, N}+\eta^{2} \bar{A}_{2}^{\star, N}+\cdots
$$

where

$$
\eta \bar{A}_{1}^{\star, N}=\frac{\eta}{\left|Q_{N}\right|} \sum_{k \in I_{N}} \mathcal{A}_{k}^{1 \operatorname{def}}
$$

is the contribution to the homogenized matrix due to all the defects in the system, considered isolated one from each other.

We see that

$$
\eta \bar{A}_{1}^{\star, N}=\mathbb{E}\left[A_{1}^{\star, N}\right]
$$

where

$$
A_{1}^{\star, N}(\omega)=\frac{1}{\left|Q_{N}\right|} \sum_{k \in I_{N}} B_{\eta}^{k}(\omega) \mathcal{A}_{k}^{1 \mathrm{def}}
$$

where $B_{\eta}^{k}=1$ if defect in cell $Q+k$ (which happens with probability $\eta$ ).

## Control variate - 2

$$
\mathbb{E}\left[A_{N}^{\star}\right]=A_{\mathrm{per}}^{\star}+\eta \bar{A}_{1}^{\star, N}+\eta^{2} \bar{A}_{2}^{\star, N}+\cdots
$$

We introduce

$$
A_{\mathrm{app}}^{\star}(\omega):=A_{\mathrm{per}}^{\star}+A_{1}^{\star, N}(\omega) \quad \text { with } \quad A_{1}^{\star, N}(\omega):=\frac{1}{\left|Q_{N}\right|} \sum_{k \in I_{N}} B_{\eta}^{k}(\omega) \mathcal{A}_{k}^{1 \mathrm{def}}
$$

notice that

$$
\mathbb{E}\left[A_{N}^{\star}\right]=\mathbb{E}\left[A_{\mathrm{app}}^{\star}\right]+\eta^{2} \bar{A}_{2}^{\star, N}+\cdots
$$

and think of $A_{\text {app }}^{\star}(\omega)$ as a good approximation of $A_{N}^{\star}(\omega)$.

This is confirmed by the fact that, for any function $\varphi$,

$$
\mathbb{E}\left[\varphi\left(A_{N}^{\star}\right)\right]=\mathbb{E}\left[\varphi\left(A_{\mathrm{app}}^{\star}\right)\right]+O\left(\eta^{2}\right) .
$$

## Control variate - 3

## Procedure:

- draw $B_{\eta}^{k}(\omega)$ in each cell $Q+k$ (defect or not?). This determines the field $A(x, \omega)$ on $Q_{N}$.
- compute the associated $A_{N}^{\star}(\omega)$ (corrector pb on $Q_{N}$ )
- build the control variate ( $\rho$ deterministic parameter)

$$
C_{N}^{\star}(\omega)=A_{N}^{\star}(\omega)-\rho\left(A_{\mathrm{per}}^{\star}+A_{1}^{\star, N}(\omega)-\mathbb{E}\left[A_{\mathrm{per}}^{\star}+A_{1}^{\star, N}(\omega)\right]\right)
$$

with $A_{1}^{\star, N}(\omega)=\frac{1}{\left|Q_{N}\right|} \sum_{k \in I_{N}} B_{\eta}^{k}(\omega) \mathcal{A}_{k}^{1 \text { def }}$
(expectation analyt. computable).

## Control variate - 4

$$
C_{N}^{\star}(\omega)=A_{N}^{\star}(\omega)-\rho\left(A_{\mathrm{per}}^{\star}+A_{1}^{\star, N}(\omega)-\mathbb{E}\left[A_{\mathrm{per}}^{\star}+A_{1}^{\star, N}(\omega)\right]\right)
$$

- Expect $A_{\mathrm{app}}^{\star}(\omega)=A_{\mathrm{per}}^{\star}+A_{1}^{\star, N}(\omega)$ to be a good approx. of $A_{N}^{\star}(\omega)$ (at least for $\eta \ll 1$ ).
- Observe that $\mathbb{E}\left[A_{N}^{\star}(\omega)\right]=\mathbb{E}\left[C_{N}^{\star}(\omega)\right]$
- IDEA: approximate $\mathbb{E}\left[A_{N}^{\star}(\omega)\right]=\mathbb{E}\left[C_{N}^{\star}(\omega)\right]$ by

$$
J_{M}=\frac{1}{M} \sum_{m=1}^{M} C_{N}^{\star}\left(\omega_{m}\right) \quad\left[\text { Confidence interval: } \operatorname{Var} C_{N}^{\star}\right]
$$

## Control variate - 4

$$
C_{N}^{\star}(\omega)=A_{N}^{\star}(\omega)-\rho\left(A_{\mathrm{per}}^{\star}+A_{1}^{\star, N}(\omega)-\mathbb{E}\left[A_{\mathrm{per}}^{\star}+A_{1}^{\star, N}(\omega)\right]\right)
$$

- Expect $A_{\mathrm{app}}^{\star}(\omega)=A_{\mathrm{per}}^{\star}+A_{1}^{\star, N}(\omega)$ to be a good approx. of $A_{N}^{\star}(\omega)$ (at least for $\eta \ll 1$ ).
- Observe that $\mathbb{E}\left[A_{N}^{\star}(\omega)\right]=\mathbb{E}\left[C_{N}^{\star}(\omega)\right]$
- IDEA: approximate $\mathbb{E}\left[A_{N}^{\star}(\omega)\right]=\mathbb{E}\left[C_{N}^{\star}(\omega)\right]$ by

$$
J_{M}=\frac{1}{M} \sum_{m=1}^{M} C_{N}^{\star}\left(\omega_{m}\right) \quad\left[\text { Confidence interval: } \operatorname{Var} C_{N}^{\star}\right]
$$

Optimal $\rho$ that minimizes the variance of (an entry of the matrix) $C_{N}^{\star}$ :

$$
\rho_{\text {opt }}=\frac{\operatorname{Cov}\left(A_{N}^{\star}, A_{1}^{\star, N}\right)}{\operatorname{Var}\left(A_{1}^{\star, N}\right)} \quad \text { well approx. by empirical mean }
$$

## Control variate based on second order approximation - 1

$$
\mathbb{E}\left[A_{N}^{\star}\right]=A_{\mathrm{per}}^{\star}+\eta{\overline{A_{1}^{\star}}}^{\star, N}+\eta^{2} \bar{A}_{2}^{\star, N}+\cdots
$$

where

$$
\eta^{2} \bar{A}_{2}^{\star, N}=\frac{\eta^{2}}{2\left|Q_{N}\right|} \sum_{k \neq \ell} \mathcal{A}_{k, \ell}^{2 \text { def }}
$$

is the contribution to the homogenized matrix due to all pairs of defects in the system, located at $k$ and $\ell$. We see that

$$
\eta^{2} \bar{A}_{2}^{\star, N}=\mathbb{E}\left[A_{2}^{\star, N}\right]
$$

where

$$
A_{2}^{\star, N}(\omega)=\frac{1}{2\left|Q_{N}\right|} \sum_{k \neq \ell} B_{\eta}^{k}(\omega) B_{\eta}^{\ell}(\omega) \mathcal{A}_{k, \ell}^{2 \text { def }}
$$

where $B_{\eta}^{k}=1$ if defect in cell $Q+k$ (which happens with probability $\eta$ ). $A_{\text {app }}^{\star}(\omega):=A_{\text {per }}^{\star}+A_{1}^{\star, N}(\omega)+A_{2}^{\star, N}(\omega)$ is such that $\mathbb{E}\left[A_{N}^{\star}\right]=\mathbb{E}\left[A_{\text {app }}^{\star}\right]+O\left(\eta^{3}\right)$.

## Control variate based on second order approximation - 2

- Second order control variate approach:

$$
C_{N}^{\star}(\omega)=A_{N}^{\star}(\omega)-\rho\left(A_{\mathrm{per}}^{\star}+A_{1}^{\star, N}(\omega)-\mathbb{E}[\ldots]\right)-\rho_{2}\left(A_{2}^{\star, N}(\omega)-\mathbb{E}[\ldots]\right)
$$

For any entry $1 \leq i, j \leq d$, optimal parameters $\rho$ and $\rho_{2}$ by minimizing $\operatorname{Var}\left(\left[C_{N}^{\star}\right]_{i j}\right)$ (inverse a $2 \times 2$ matrix).

- Here, we systematically refer to the situation "no defect", $\eta \ll 1$. It is also possible to refer to the situation "all defects", $1-\eta \ll 1$.

The first order correction turns out to be the same, but not the second order correction:

$$
\begin{aligned}
C_{N}^{\star}(\omega)=A_{N}^{\star}(\omega)-\rho\left(A_{\mathrm{per}}^{\star}+A_{1}^{\star, N}(\omega)\right) & -\rho_{2} A_{2, \text { wrt } \eta=0}^{\star, N}(\omega) \\
& -\rho_{3} A_{2, \text { wrt } \eta=1}^{\star, N}(\omega)-\mathbb{E}[\ldots]
\end{aligned}
$$

## Numerical test case

## 

$A(x, \omega)=\sum_{k \in \mathbb{Z}^{2}} 1_{Q+k}(x) a_{k}(\omega) \operatorname{Id}_{2}, \quad a_{k}$ independent identically distributed
$\mathbb{P}\left(a_{k}=\alpha\right)=\eta, \quad \mathbb{P}\left(a_{k}=\beta\right)=1-\eta$.
Not always clear to decide who is the defect / background (e.g. when $\eta=1 / 2)$.

## Small contrast test case: $(\alpha, \beta)=(3,23)$ - Homogenized coefficient

Blue curve: standard Monte Carlo estimator $I_{M}^{\mathrm{MC}}=M^{-1} \sum_{m=1}^{M} A_{N}^{\star}\left(\omega_{m}\right)$ Black curves: weakly stochastic approximation (expansion wrt $\eta=0$ or $\eta=1$ ): inaccurate when $0.4 \leq \eta \leq 0.7$.

## Ratios $\operatorname{Var}\left(A_{N}^{\star}\right) / \operatorname{Var}\left(C_{N}^{\star}\right) \equiv$ CPU time gain

Black curves: control variate approach using first order approximation.
Red curves: control variate approach using second order approximation (wrt $\eta=0$ OR $\eta=1$ ).

Blue curve: control variate approach simultaneously using first and second order approximations at both ends ( $\eta=0$ AND $\eta=1$ ).

## Small contrast test case: $(\alpha, \beta)=(3,23)$ - Efficiency at $\eta=1 / 2$

$$
\begin{aligned}
C_{N}^{\star}(\omega) & =A_{N}^{\star}(\omega)-\rho\left(A_{\mathrm{per}}^{\star}+A_{1}^{\star, N}(\omega)-\mathbb{E}[\ldots]\right) \\
& -\rho_{2}\left(A_{2, \text { wrt. } \eta=0}^{\star, N}(\omega)-\mathbb{E}[\ldots]\right)-\rho_{3}\left(A_{2, \text { wrt. } \eta=1}^{\star}(\omega)-\mathbb{E}[\ldots]\right)
\end{aligned}
$$

- Control variate using first order approximation ( $\rho_{2}=\rho_{3}=0$ ):
- variance ratio $=6$
. computing the control variate is inexpensive, hence

$$
\text { CPU time gain }=\text { Variance ratio }=6
$$

- Control variate using second order approximation (optimal $\rho, \rho_{2}$ and $\rho_{3}$ ):
- variance ratio $=44$
- using a RB approach (Le Bris \& Thomines, 2012), computing the control variate is inexpensive:

CPU time gain $=$ Variance ratio $=44$

## Robustness ( $\eta=1 / 2$ ) wrt supercell size

Variance reduction ratio (first order or second order approximation): insensitive to the supercell size.

## Large contrast test case: $(\alpha, \beta)=(3,103)$ - Homogenized coefficient

Blue curve: standard Monte Carlo estimator $I_{M}^{\mathrm{MC}}=M^{-1} \sum_{m=1}^{M} A_{N}^{\star}\left(\omega_{m}\right)$
Black curves: weakly stochastic approximation (with $\alpha$ or $\beta$ as background): inaccurate when $0.3 \leq \eta \leq 0.7$.

## Variance ratios (CPU time gain)

Black curves: control variate approach using first order approximation
Red curves: control variate approach using second order approximation (wrt $\eta=0$ OR $\eta=1$ ).

## Quantitative estimation of the variance reduction ( $\eta \ll 1$ )

Three approaches to compute $\mathbb{E}\left[A_{N}^{\star}\right]$ :

- Standard Monte Carlo approach with $M$ realizations:

$$
\text { error }=\text { statistical error } \propto \sqrt{\operatorname{Var}\left(A_{N}^{\star}\right) / M} \propto \sqrt{\eta / M}
$$

## Quantitative estimation of the variance reduction ( $\eta \ll 1$ )

Three approaches to compute $\mathbb{E}\left[A_{N}^{\star}\right]$ :

- Standard Monte Carlo approach with $M$ realizations:

$$
\text { error }=\text { statistical error } \propto \sqrt{\operatorname{Var}\left(A_{N}^{\star}\right) / M} \propto \sqrt{\eta / M}
$$

- Control Variate approach (first order) with $M$ realizations:

$$
\text { error }=\text { statistical error } \propto \sqrt{\operatorname{Var}\left(C_{N}^{\star}\right) / M} \propto \sqrt{\eta^{2} / M}
$$

At equal cost, more accurate that Monte Carlo.

## Quantitative estimation of the variance reduction ( $\eta \ll 1$ )

Three approaches to compute $\mathbb{E}\left[A_{N}^{\star}\right]$ :

- Standard Monte Carlo approach with $M$ realizations:

$$
\text { error }=\text { statistical error } \propto \sqrt{\operatorname{Var}\left(A_{N}^{\star}\right) / M} \propto \sqrt{\eta / M}
$$

- Control Variate approach (first order) with $M$ realizations:

$$
\text { error }=\text { statistical error } \propto \sqrt{\operatorname{Var}\left(C_{N}^{\star}\right) / M} \propto \sqrt{\eta^{2} / M}
$$

At equal cost, more accurate that Monte Carlo.

- Expansion of $\mathbb{E}\left[A_{N}^{\star}\right]$ (Anantharaman / Le Bris) using the same information as the Control Variate approach:
$\mathbb{E}\left[A_{N}^{\star}\right]=A_{\mathrm{per}}^{\star}+\eta \bar{A}_{1}^{\star, N}+O\left(\eta^{2}\right), \quad$ error $=$ systematic error $\propto \eta^{2}$.
CV approach needs $M \propto 1 / \eta^{2} \gg 1$ to reach a similar accuracy.
Regime of interest for our CV approach: $\eta$ neither close to 0 nor 1 .

## Conclusions

- We have proposed a control variate approach based on a defect-type model to better compute $\mathbb{E}\left[A_{N}^{\star}\right]$.
- When none of the phase dominates ( $\eta \approx 1 / 2$ ), the defect model becomes inaccurate per se, but remains useful as a control variate.

In a nutshell: use a weakly stochastic model to improve efficiency for fully stochastic cases.

- For the moment, all computations have been done with the exact $A_{2}^{\star, N}(\omega)$. If we indeed use the RB approach, what impact on the variance reduction?
Up to what can we degrade the surrogate model?
