Hybrid High-Order methods for finite deformations of hyperelastic materials

Mickaël Abbas, Alexandre Ern, Nicolas Pignet

EDF R&D - IMSIA CERMICS - INRIA

ECCM 6, Glasgow, 13.06.18

Context

- Nonlinear hyperelastic problem
 - measure of the deformations (geometric nonlinearity)
 - stress-strain constitutive relation (material nonlinearity)
- Presence of volumetric-locking with primal H¹-conforming formulation in the incompressible limit λ → +∞ (ν ≃ 0.5)
- An alternative : using mixed methods but more unknowns, more expensive to build, saddle-point problem to solve ...

Figure 1 – Trace of the stress tensor for (a) P1 (b) P2 (c) P2/P1/P1

Some references on primal formulations without volumetric-locking

- discontinuous Galerkin (dG)
 - [Noels, Radovitzsky 06]
 - [ten Eyck, Lew 06]
- Hybridizable Discontinuous Galerkin (HDG)
 - [Nguyen, Peraire 12]
 - [Kabaria, Lew, Cockburn 15]
- Virtual Element Method (VEM)
 - [Chi, Beirão da Veiga, Paulino 17]
 - [Wriggers, Reddy, Rust, Hudobivnik 17]

Key ideas of Hybrid High-Order (HHO) methods

- Primal formulation with cells and faces unknowns
- Local reconstruction and stabilization
 - Gradient tensor field reconstructed in $\mathbb{P}_d^k(T; \mathbb{R}^{d \times d})$
 - Stabilization connecting cell and faces unknowns
- References
 - diffusion problem [Di Pietro, Ern, Lemaire, CMAM 14]
 - quasi-incompressible linear elasticity [Di Pietro, Ern, CMAME 15]
 - nonlinear elasticity with small def. [Botti, Di Pietro, Sochala, SINUM 17]

Figure 2 - Face (green) and Cell (blue) unknowns

Features of HHO methods

- Support of polytopal meshes (with possibly nonconforming interfaces)
- Arbitrary approximation order $k \ge 1$
 - h^{k+1} convergence in energy-norm
 - h^{k+2} convergence in L^2 -norm with elliptic regularity
- Dimension-independent construction
- Attractive computational costs
 - Compact stencil (only neighbourhood faces)
 - Cell unknowns are eliminated locally by static condensation
 - Reduced size $N_{dofs}^{hho} \approx k^2 \operatorname{card}(\mathcal{F}^h)$ vs. $N_{dofs}^{dG} \approx k^3 \operatorname{card}(\mathcal{T}^h)$
- Local principle of virtual work (equilibrated tractions)
- HHO methods are bridged to HDG and ncVEM
 - [Cockburn, Di Pietro, Ern 16]

Hyperelasticity problem

- Let $\Omega_0 \in \mathbb{R}^d$ (d=2,3), be a bounded connected polytopal domain
- Let \underline{f} and \underline{t} be given volumetric and surface (on Γ_n) loads
- Let $\underline{\boldsymbol{u}}_D$ be a given imposed displacement on Γ_d
- We define the energy functional \mathcal{E} in the reference configuration for all $\underline{\boldsymbol{v}} \in V := \left\{ \underline{\boldsymbol{v}} \in H^1(\Omega_0, \mathbb{R}^d) \, | \, \underline{\boldsymbol{v}} = \underline{\boldsymbol{u}}_D \text{ on } \Gamma_d \right\}$

$$\mathcal{E}(\underline{\boldsymbol{\nu}}) := \int_{\Omega_{\mathbf{0}}} \Psi(\underline{\boldsymbol{F}}(\underline{\boldsymbol{\nu}})) - \int_{\Omega_{\mathbf{0}}} \underline{\boldsymbol{f}} \cdot \underline{\boldsymbol{\nu}} \, d\Omega_{\mathbf{0}} - \int_{\Gamma_{n}} \underline{\boldsymbol{t}} \cdot \underline{\boldsymbol{\nu}} \, d\Gamma.$$

with $\underline{\underline{F}} := \underline{\underline{\nabla}}_{X} \underline{\underline{u}} + \underline{\underline{I}}_{d}$ and a strain energy density $\Psi : \mathbb{R}^{d \times d}_{+} \to \mathbb{R}$ • Example of Neohookean strain energy density

$$\Psi(\underline{\underline{F}}) = \frac{\mu}{2} \left(\underline{\underline{F}} : \underline{\underline{F}} - d\right) - \mu \ln(\det \underline{\underline{F}}) + \frac{\lambda}{2} (\ln(\det \underline{\underline{F}}))^2,$$

with $\mu > 0$, $\lambda > 0$ (material constants)

- \bullet We assume that Ψ is polyconvex, i.e. existence of local minimizers
- Static equilibrium : stationary point(s) \underline{u} of the energy \mathcal{E}

 $D\mathcal{E}(\underline{\boldsymbol{u}})[\delta \underline{\boldsymbol{v}}] = 0, \, \forall \delta \underline{\boldsymbol{v}} \in H_0^1(\Omega_0, \mathbb{R}^d)$

• Weak problem : Find $\underline{u} \in V$ such that for all $\delta \underline{v} \in H_0^1(\Omega_0, \mathbb{R}^d)$

$$\int_{\Omega_{\mathbf{0}}} \underline{\underline{P}}(\underline{\underline{F}}(\underline{u})) : \underline{\underline{\nabla}}_{X}(\delta \underline{v}) \, d\Omega_{\mathbf{0}} = \int_{\Omega_{\mathbf{0}}} \underline{\underline{f}} \cdot \delta \underline{\underline{v}} \, d\Omega_{\mathbf{0}} + \int_{\Gamma_{n}} \underline{\underline{t}} \cdot \delta \underline{\underline{v}} \, d\Gamma.$$

with $\underline{\underline{P}}=\partial_{\underline{\underline{F}}}\Psi$ the first Piola–Kirchhoff stress tensor

Local DOFs space

- Let M^h := (T^h, F^h) be a mesh of Ω₀ with T^h the set of cells and F^h the set of faces
- Let a polynomial degree $k \geq 1$, for all $T \in \mathcal{T}^h$

Figure 3 – Local DOFs for k = 1, 2. Cell unknowns eliminated by static condensation

Gradient reconstruction

- The reconstructed gradient $\underline{\underline{G}}_{T}^{k}(\underline{\underline{v}}_{T}, \underline{\underline{v}}_{\partial T})$ solves, $\forall \underline{\underline{\tau}} \in \mathbb{P}_{d}^{k}(T; \mathbb{R}^{d \times d})$ $(\underline{\underline{G}}_{T}^{k}(\underline{\underline{v}}_{T}, \underline{\underline{v}}_{\partial T}), \underline{\underline{\tau}})_{\underline{\underline{L}}^{2}(T)} = (\underline{\underline{\nabla}}_{X} \underline{\underline{v}}_{T}, \underline{\underline{\tau}})_{\underline{\underline{L}}^{2}(T)} + (\underline{\underline{v}}_{\partial T} - \underline{\underline{v}}_{T}, \underline{\underline{\tau}}, \underline{\underline{n}}_{T})_{\underline{\underline{L}}^{2}(\partial T)}.$
 - local scalar mass-matrix of size $\binom{k+d}{k}$ to invert (ex : k = 2, d = 3, size = 10)
- We define $\underline{\underline{F}}_{T}^{k}(\underline{\underline{v}}_{T}, \underline{\underline{v}}_{\partial T}) := \underline{\underline{G}}_{T}^{k}(\underline{\underline{v}}_{T}, \underline{\underline{v}}_{\partial T}) + \underline{\underline{I}}_{d} \in \mathbb{P}_{d}^{k}(T; \mathbb{R}^{d \times d})$
- Local discrete counterpart $\mathcal{E}_T^{mech} : \underline{U}_T^k \to \mathbb{R}$ of the energy \mathcal{E}

$$\mathcal{E}_{T}^{mech}(\underline{\boldsymbol{v}}_{T},\underline{\boldsymbol{v}}_{\partial T}) = \int_{T} \left\{ \Psi(\underline{\boldsymbol{F}}_{T}^{k}(\underline{\boldsymbol{v}}_{T},\underline{\boldsymbol{v}}_{\partial T})) - \underline{\boldsymbol{f}}\cdot\underline{\boldsymbol{v}}_{T} \right\} \, dT - \int_{\partial T \cap \mathcal{F}_{b,n}^{h}} \underline{\boldsymbol{t}}\cdot\underline{\boldsymbol{v}}_{\partial T} \, d\partial T$$

• Problem :
$$\underline{\underline{G}}_{T}^{k}(\underline{\underline{v}}_{T}, \underline{\underline{v}}_{\partial T}) = \underline{\underline{0}} \Rightarrow \underline{\underline{v}}_{T} = \underline{\underline{v}}_{\partial T} = \text{cste}$$

• \Rightarrow We have to add a stabilization term

Hence, we penalize the difference between the faces unknowns and the trace of the cell unknowns : <u>θ</u> := <u>v</u>_{∂T} - <u>v</u>_{T|∂T} ∈ P^k_{d-1}(F_{∂T}; ℝ^d),

$$\underline{\boldsymbol{S}}_{\partial T}^{k}(\underline{\boldsymbol{\theta}}) = \underline{\boldsymbol{\Pi}}_{\partial T}^{k}(\underline{\boldsymbol{\theta}} - (\underline{\underline{\boldsymbol{\ell}}}_{d} - \underline{\boldsymbol{\Pi}}_{T}^{k})\underline{\boldsymbol{D}}_{T}^{k+1}(\underline{\boldsymbol{0}},\underline{\boldsymbol{\theta}}))$$

where $\underline{\Pi}_{\partial T}^{k}$ is the L^{2} -projector on ∂T , $\underline{\Pi}_{T}^{k}$ the L^{2} -projector on T, and \underline{D}_{T}^{k+1} is a reconstructed displacement field

• We define the local stabilization energy $\mathcal{E}_T^{stab}: \underline{U}_T^k \to \mathbb{R}$

$$\mathcal{E}_{T}^{stab}(\underline{\boldsymbol{v}}_{T},\underline{\boldsymbol{v}}_{\partial T}) = \frac{h_{T}^{-1}}{2} \|\underline{\boldsymbol{S}}_{\partial T}^{k}(\underline{\boldsymbol{v}}_{\partial T}-\underline{\boldsymbol{v}}_{T|\partial T})\|_{\underline{\boldsymbol{L}}^{2}(\partial T)}^{2}$$

Global DOFs space and discrete energy

• We define the global space by patching the interface DOFs

$$(\underline{\boldsymbol{\nu}}_{\mathcal{T}^{h}}, \underline{\boldsymbol{\nu}}_{\mathcal{F}^{h}}) \in \underbrace{\underline{\boldsymbol{\mathcal{U}}}_{h}^{k}}_{\text{global HHO dofs}} := \underbrace{\left\{ \underset{T \in \mathcal{T}^{h}}{\times} \mathbb{P}_{d}^{k}(T; \mathbb{R}^{d}) \right\}}_{\text{global cells dofs}} \times \underbrace{\left\{ \underset{F \in \mathcal{F}^{h}}{\times} \mathbb{P}_{d-1}^{k}(F; \mathbb{R}^{d}) \right\}}_{\text{global faces dofs}}$$

and its subspaces $\underline{U}_{h,d}^k$ and $\underline{U}_{h,0}^k$ by imposing strongly the BC on Γ_d .

• We define the global discrete energy $\mathcal{E}_h: \underline{\boldsymbol{U}}_h^k o \mathbb{R}$

$$\underbrace{\mathcal{E}_{h}(\underline{\boldsymbol{\nu}}_{\mathcal{T}^{h}},\underline{\boldsymbol{\nu}}_{\mathcal{F}^{h}})}_{\text{global discrete energy}} = \underbrace{\sum_{T \in \mathcal{T}^{h}} \mathcal{E}_{T}^{mech}(\underline{\boldsymbol{\nu}}_{T},\underline{\boldsymbol{\nu}}_{\partial T})}_{\text{global mech. discrete energy}} + \underbrace{\sum_{T \in \mathcal{T}^{h}} \beta \, \mathcal{E}_{T}^{stab}(\underline{\boldsymbol{\nu}}_{T},\underline{\boldsymbol{\nu}}_{\partial T})}_{\text{global stabilization energy}}$$

with β an user-dependent stabilization parameter (can be hard to choose)

• We search the stationary point(s) of \mathcal{E}_h

$$D\mathcal{E}_{h}(\underline{\boldsymbol{u}}_{\mathcal{T}^{h}},\underline{\boldsymbol{u}}_{\mathcal{F}^{h}}))[(\delta\underline{\boldsymbol{v}}_{\mathcal{T}^{h}},\delta\underline{\boldsymbol{v}}_{\mathcal{F}^{h}})]=0,\,\forall(\delta\underline{\boldsymbol{v}}_{\mathcal{T}^{h}},\delta\underline{\boldsymbol{v}}_{\mathcal{F}^{h}})\in\underline{\boldsymbol{U}}_{h,0}^{k}$$

• Find $(\underline{\textit{u}}_{\mathcal{T}^h}, \underline{\textit{u}}_{\mathcal{F}^h}) \in \underline{\textit{U}}_{h,d}^k$ such that

$$\begin{split} &\sum_{T\in\mathcal{T}^{h}} (\underline{\underline{P}}(\underline{\underline{F}}_{T}^{k}(\underline{u}_{T},\underline{u}_{\partial T})), \underline{\underline{G}}_{T}^{k}(\delta\underline{v}_{T},\delta\underline{v}_{\partial T}))_{\underline{\underline{I}}^{2}(T)} \\ &+ \sum_{T\in\mathcal{T}^{h}} \beta h_{T}^{-1} (\underline{\underline{S}}_{\partial T}^{k}(\underline{u}_{\partial T}-\underline{u}_{T\mid\partial T}), \underline{\underline{S}}_{\partial T}^{k}(\delta\underline{v}_{\partial T}-\delta\underline{v}_{T\mid\partial T}))_{\underline{\underline{I}}^{2}(\partial T)} \\ &= \sum_{T\in\mathcal{T}^{h}} (\underline{\underline{f}},\delta\underline{v}_{T})_{\underline{\underline{I}}^{2}(T)} + \sum_{F\in\mathcal{F}_{b,n}^{h}} (\underline{\underline{t}},\delta\underline{v}_{F})_{\underline{\underline{I}}^{2}(F)}, \quad \forall (\delta\underline{v}_{\mathcal{T}^{h}},\delta\underline{v}_{\mathcal{F}^{h}}) \in \underline{\underline{U}}_{h,0}^{k} \end{split}$$

- Nonlinear problem to solve (geometric and material nonlinearites)
- Iterative resolution with a Newton method (SPD global system)
- Static condensation performed at each Newton's iteration
- Offline computations (gradient and stabilization operators precomputed)
- Implementation in the open-source library disk++
- Verification on analytical solutions :
 - Expected convergence rates $(h^{k+1} \text{ in energy-norm and } h^{k+2} \text{ in } L^2\text{-norm})$
 - Absence of volumetric-locking in the quasi-incompressible regime
- Tested on more challenging 3D test cases (see [Kabaria, Lew, Cockburn 15])

Quasi-incompressible annulus I

- Analytical solution
- Imposed radial displacement on the inner circumference

Figure 4 – Solution for k = 1 and $\nu = 0.4999$

Quasi-incompressible annulus II

Figure 5 – errors vs. λ on a fixed mesh

- The errors do not depend on λ
 - \Rightarrow HHO methods are robust in the incompressible limit

Nicolas Pignet

Sheared and compressed cylinder ($\nu = 0.45$)

- The bottom face is clamped
- Imposed vertical and horizontal displacement on the top face

Figure 6 - Snapshots of the displacement at 0%, 40%, 80% and 100% of loading

Sphere with cavitating voids

- Growth of internal cavities under large tensile stresses
- Conforming FEM are not really robust
- Imposed radial displacement on the outer surface
- We stop when the Newton's method fails to converge

Figure 7 – Displacement for k = 2 at the different steps (around 250% of deformations)

- Original idea for dG : [John, Neilan, Smears 16]
 - Based on the properties of the Raviart-Thomas space
- Gradient reconstruction in $\mathbb{P}_d^{k+1}(T; \mathbb{R}^{d \times d})$ (larger space)
 - ex : k = 2, d = 3, size = 20 for $\mathbb{P}_d^{k+1}(T; \mathbb{R}^{d \times d})$ vs 10 for $\mathbb{P}_d^k(T; v^{d \times d})$
- No additional stabilization is needed
- Lower convergence rates (h^k in energy-norm and h^{k+1} in L^2 -norm)
- Comparable numerical cost vs. stabilized HHO (sHHO) methods
- Better results for the cavitation problem ($r_{max} = 2.52$ vs. $r_{max}^{SHHO} = 2.13$)

• Conclusion :

- Adaptation of HHO methods to hyperelastic material with finite deformations
- Absence of volumetric-locking
- Variant of HHO method without stabilization
- Perspectives of this work :
 - Extension to finite plasticity
 - Introduction of contact and friction
 - Implementation in code_aster (in progress)
